THE
PRACTICE
OF
PERSPECTIVE,

On the PRINCIPLES of

Dr. BROOK TAYLOR:

IN

A series of examples, from the most simple, and easy, to the most complicated, and difficult cases,

In the course of which, his method is compared with those of some; of the most celebrated writers, before him, on the subject.

Written many years since, but now first published,

By JOSEPH HIGHMORE.

LONDON,

Printed for A. MILLAR, and J. NOURSE, in the Strand.

MDCCLXIII.

T H E

P R E F A C E.

THERE are, already, so many treatises on perspective, that perhaps it may seem needless to add to the number; and it might justly be thought impertinent to offer any thing to the public, on this subject, after Dr. Brook Taylor; unless the end proposed were different from his, and consequently different means necessary.

He has invented, and, in a very short compass, exhibited an universal theory; the truth, and excellence, of which is acknowledged by all who have read, and considered it, at the same time that they complain of its obscurity. The attention, and application which the reading, and understanding this little book require, especially with such as are but little conversant in geometry, has discouraged the generality of those, for whose service it was chiefly designed, from the attempt; so that very few have profited by the best treatise that has been published on the subject.

It was first printed in 1715, and again in 1719, with some difference, in order to render it less difficult, objections having been made to the former edition, on account of its intricacy: neither of the impressions is entirely sold, if we are rightly informed*. But though this author has been studied by few, yet with these he is in the highest esteem, as the inventor of the true universal system.

Now if that, (the most excellent of all books on the subject,) has been liable to such objections, as to make the labours of later

* Since the above was written, there has been another edition of Dr. Brook Taylor, published in 1749, said to be revised, and corrected by Mr. Colson, of Cambridge.

writers,

writers, on the same principles, acceptable to the public, the author hopes that this tract (the first written after Brook Taylor's, as he has reason to believe, though last published) will be received with candour: And especially because, though his design, in general, be the same with theirs, his manner of treating the subject has been very different, as he had conceived it might be more naturally adapted to the comprehension of learners, for whose use it was principally intended.

His purpose, and endeavour, has been to give the surest, and shortest rules for representing all sorts of objects, and this in a popular, familiar manner, without constant strict mathematical demonstrations; although illustrations, and even demonstrations, are not omitted, where they have been thought necessary.

He had, originally, intended to supply only what was wanting in the old perspective, which might have been acceptable to those already experienced in the art, but would have been wholly useless to others. And since many have been discouraged from the study, by hearing of the deficiency of the old method, and the difficulty of comprehending the new, he judged it better to make his work as complete in its kind, as he could; so as to enable any one, with a common application, to represent objects, in all possible situations, with the fewest lines that the nature of the thing will admit, and without the assistance of any other book.

With this view he hath, in the first part, given a few examples in a manner common to the old, and new system, and has endeavoured to explain even this as clearly, and comprehensively as possible, both to render it easy to the learner, and also to prepare him more effectually for the other method.

In the second part, objects are represented in both methods, separately, to shew the advantage of the new, not only where the old is false, but also where it is incumbered with unnecessary lines, and points, for want of the true, universal principles: here, examples are taken from Pozzo, and the Jesuit, the two most celebrated, and most studied authors; as also from A. Bosse, an
old

old French writer, by some, much esteemed, from whom the Jesuit has borrowed, with proper acknowledgment to the merit of Mons. Desargues, on whose principles Bossie professes to have written. And in the course of this part, several mistakes of these authors are remarked.

This second part may be considered as a comparative perspective, and will be acceptable to those who are already acquainted with most of the methods of projection, though they may not have taken the pains to make such comparison; but it is principally designed to shew the great advantages of the new method, and to excite the students, in this science, to render themselves masters of it; which, although it may require more application at first, will enable them, afterwards, to execute whatever they undertake with more certainty, and expedition, than any other.

Those whose curiosity may not detain them to examine the several schemes of this second part, may pass directly from the first, to the third part; wherein the five regular solids are projected; which examples are chosen, as furnishing occasion for almost every case that has any difficulty, in perspective; insomuch, that whoever fully comprehends the diagrams, -and can project these objects, will (it is apprehended) find the projection of all others easy.

In this, and the following parts, are many things which the author presumes are entirely new, at least, he has never met with them elsewhere.

The learner, however, is advised, not to content himself with a mere inspection of the diagrams, nor even with performing the problems as here exhibited, only, but to project the same objects in various situations, till he finds himself perfect both in the principles and practice; he is also advised, to begin these operations with a small distance, that so all, or most, of the vanishing points may be found within the limits of his paper; but when he shall have acquired a facility in the execution, he may take what distance he pleases, and if any difficulties arise, on that, or any other circumstance, he will find in the next,

And fourth part, expedients for them, this being the place frequently referred to, in the course of the treatise, for obviating several inconveniencies that may happen from want of space, as well as for many other schemes, of great utility in practice; these were reserved for this part on purpose, that the learner, by having gradually advanced thus far, might be more sensible of their usefulness, and so apply himself with the more eagerness, and pleasure, to comprehend them.

The fifth, and last part, treats of the manner of finding the shadows of objects on divers planes, and the images of objects in reflecting planes, but briefly, as being of less use than the former parts, which are absolutely necessary. Both shadows, and reflections, are wholly omitted by POZZO, though so great a master in the practice of perspective. The Jesuit has examples of shadows cast on planes, but is strangely mistaken in some of them, as well as in the precepts with which they are accompanied, as is shewn, where they are particularly mentioned.

A D V E R T I S E M E N T.

As the Author was near sixty miles from London, while this Work was printing, it is hoped the following errors of the press will be the more easily excused: And the Reader is particularly desired to correct them, with his pen, before he begins the book, because the smallest errors, in these Subjects, perplex the sense, and in some cases entirely pervert it; especially where letters of reference are mistaken.

T H E

I N T R O D U C T I O N.

SINCE the completion of this treatise in the order proposed, it has been thought proper to prefix a few of the first principles of geometry, to facilitate the progress of such readers who may not have been conversant in these studies.

Definitions from *Euclid's* Elements.

- Fig. 1. 1. A point is considered as having no parts, as A.
 2. A line is considered as having no breadth, as A, B.
 3. The extremities of a line are points.
 4. A right (or straight) line, is that which lies equally between its points, or is the shortest that can be drawn from point to point, as A, B, fig. 2.
 5. A superficies is that which hath only length and breadth, without depth, or thickness, as A, B, C, D, fig. 3.
 6. The extremes or ends of a superficies are lines.
 7. A plain superficies is that which lies equally between its lines.
 8. A plain angle, B, A, C, is an inclination of two lines in a plane to each other, as A, B, and A, C, the one touching the other, as in the point A, fig. 4.
N. B. The second, or middle letter, is always the angular point.
 9. When the lines which contain the angle are right (or straight) lines, it is called a right-lined angle.
 If both be curved, it is a curve-lined angle; if one be curved, and the other right, it is a mixed angle.

Fig. 10. When a right line, as A, B, standing upon a right line, as C, D, makes the angles on each side equal, then both of them are right angles, and the right line A, B, is called a perpendicular to C, D, fig. 5.

11. An obtuse angle is that which is greater than a right angle, as E, B, C, fig. 5.

12. An acute angle is that which is less than a right angle, as E, B, D, fig. 5.

13. A circle is a plain figure comprehended by one line, which is called a circumference, to which all right lines drawn from the point in the middle of the figure (called its center) are equal, as C, A,—C, B,—C, D, fig. 6.

14. The diameter of a circle is a right line, as A, B, drawn through the center C, and being terminated by the circumference, on either side, divides the circle into two equal parts.

15. A semicircle is contained by the diameter, and half the circumference, as A, D, B, fig. 6.

16. Of trilateral, or three sided figures, that which hath three equal sides, is called an equilateral triangle, as A, B, C, fig. 7.

17. That which hath only two sides equal is called an isosceles triangle, as A, B, C, fig. 8.

18. And that which hath all the three sides unequal, is called a scalenum, as A, B, C, fig. 9.

19. But that which hath one angle right is called a right-angled triangle, as A, B, C, fig. 10.

And the side opposite to the right angle is called the hypotenuse, as A, B.

20. Of quadrilateral figures, the square is that which hath the four sides equal, and the four angles right, as A, B, C, D, fig. 11.

21. An oblong, or long square, is rectangled, but not equilateral, as A, B, C, D, fig. 12.

22. A rhombus, is a figure equilateral, but not right-angled, as A, B, C, D, fig. 13.

A. *Fig. 1.*

Fig. 23. A rhomboides, hath the opposite sides and angles equal, but is neither equilateral, nor right angled, as A, B, C, D, fig. 14.

24. All other quadrilateral figures (being irregular) are called trapeziums, as A, B, C, D, fig. 15.

25. Parallels are right lines in the same plane, which being infinitely prolonged on both parts, would never meet, as A, B and C, D, fig. 16.

26. A parallelogram is a quadrilateral figure, whose opposite sides are parallel, as A, B, C, D, fig. 12, and 14.

27. When in a parallelogram, as A, B, C, D, fig. 17. there is drawn a diameter (or diagonal) A, C, and two right lines G, H, and F, E, parallel to the sides, cutting the diameter in the same point I, so that the parallelogram be divided into four parallelograms, those two, I, E, D, H, and I, F, B, G, through which the diameter doth not pass, are called *complements*, but the two others, I, E, A, G, and I, F, C, H, through which it doth pass, are said to be *about the diameter*.

Some Propositions from the first, second, third, and sixth, books of *Euclid's* Elements.

PROP. I. PROBLEM.

Upon a given right line A, B, (fig. 18.) to make an equilateral triangle A, B, C.

On the center A, at the distance A, B, describe the circle B, C, D, and on the center B, at the same distance B, A, describe the circle A, C, E, and from the point C, where the circles intersect one another, draw the two right lines C, A, and C, B. Then A, B, C, will be an equilateral triangle.

For A, C, and C, B, are each equal to A, B, by construction.

PROP. IX. PROBLEM.

To divide a given right-lined angle B, A, C, (fig. 19.) into two equal parts.

Let there be taken, in the line A, B , a point at pleasure, D , and on A, C , cut off A, E , equal to A, D , (by setting one foot of the compasses on A , and with the other describing the arc D, E ;) draw the right line D, E , and on it make an equilateral triangle D, F, E , and draw A, F , which will divide B, A, C , into two equal angles. Or the points D , and E , being found, the right line D, E , may be omitted; and instead of whole circles (as at the first Prop. fig. 18.) only mark the intersection at F , as in this figure.

P R O P. X. P R O B L E M.

To divide a given right line A, B , (fig. 20.) into two equal parts. *Euclid* directs here also to make an equilateral triangle A, C, B , on the given line, and then to divide the angle C , as in the last proposition; that is, by means of another equilateral triangle below the line; but if the angular points above and below are found by intersection, it is sufficient.

P R O P. XI. P R O B L E M.

On a given right line A, B , (fig. 21.) and from a given point therein C , to raise a perpendicular C, F .

In the part C, A , take any point D , and let C, E , be taken equal to C, D ; then, on D, E , describe the equilateral triangle D, F, E , and draw C, F , which will be perpendicular to A, B .

To raise a perpendicular at the end of a line A, D , fig. 11. With any opening of the compasses A, D , describe the arc D, e, f , and with the same opening the arc D, e , and again with the same opening e, f ; lastly, with the same e, g , and f, g , now draw g, A , which will be perpendicular to A, D .

P R O P. XII. P R O B L E M.

On a given right line A, B , (fig. 22.) and from a given point C , which is not in it, to draw a perpendicular line C, F .

Let any point H , be taken on the other side of A, B , and from the point C , as a center, at the distance C, H , describe the circle D, H, E ,
cutting

cutting A, B, in the points D, and E, and divide D, E, into two equal parts in F, and draw C, F, which will be perpendicular to A, B.

PROP. XIII. THEOREM.

When a right line E, B, (fig. 5.) falls on another right line C, D, either it makes two right angles, or two angles equal to two right angles.

DEM. For if the angle E, B, D, be equal to E, B, C, they shall be both right angles; but if it be unequal, let A, B, be drawn at right angles to C, D, then A, B, D, and A, B, C, shall be right angles. Now since E, B, D, and E, B, A, (taken together) are equal to the right angle A, B, D, if the common angle A, B, C, be added, then the three angles E, B, D,—E, B, A, and A, B, C, shall be equal to the two right angles A, B, D, and A, B, C. And since the angle E, B, C, is equal to the two angles E, B, A, and A, B, C, if you add the common E, B, D, the two angles E, B, D, and E, B, C, shall be equal to the three angles E, B, D,—E, B, A, and A, B, C. But these three have been shewn to be equal to two right angles; therefore E, B, D, and E, B, C, shall be also equal to two right angles. Which was to be demonstrated.

PROP. XXII. PROBLEM.

To constitute a triangle F, G, K, (fig. 23.) of three right lines equal to three given right lines A, B, and C.

Draw an indefinite right line D, E, and on it make D, F, equal to A,—F, G, equal to B, and G, E, equal to C; and from F, as a center, with the length F, D, describe a circle D, K, L: again, from the center G, with the length G, E, describe the circle E, K, L, and draw F, K and G, K; then the triangle F, G, K, is made of three lines equal to A, B, and C.

PROP. XXIII. PROBLEM.

On a given right line A, B, (fig. 24.) and at a point given, A, to make an angle F, A, G, equal to a given angle D, C, E.

Set one foot of the compasses on C, and with the other foot, at any distance, describe the arc E, D; then, with the same opening, set one foot on A, and describe the arc G, F. Take, with the compasses, the distance D, E, and set it off from G, to F, and draw A, F; then the angle F, A, G will be equal to E, C, D.

P R O P. XXXI. P R O B L E M.

Through a given point A, (fig. 25.) to draw a parallel to a given right line B, C.

From A, draw an oblique line A, D, to the line B, C, and from D, with the distance D, A, describe the arc A, B; then from A, with the same distance, describe the arc D, E, make D, E, equal to A, B, and draw A, E, which will be parallel to B, C.

P R O P. XXXII. T H E O R E M.

Of every triangle, as A, B, C, (fig. 26.) (one side B, being prolonged) the exterior angle A, C, D, is equal to the two interior, and opposite angles A, and B.

And the three angles of any triangle, as A, B, C, are equal to two right angles.

For having drawn C, E, parallel to A, B, it is evident that E, C, D, must be equal to A, B, C, and also that the angle A, C, E, must be equal to C, A, B. *This is not here strictly demonstrated, nor is that necessary in this introduction, but the reader is referred to the preceding propositions, in Euclid, for farther satisfaction.* Therefore the exterior angle A, C, D, (composed of them both) must be equal to A, and B; which is the first assertion.

Again. Since the angle A, C, D, and the angle A, C, B, taken together, are equal to two right angles (by Prop. XIII.) and since the angle A, C, D, is equal to the angles A, and B, (as above) it follows that the angles A, B, and A, C, B, which is common, (the three angles of any triangle,) are equal to two right; which was the second assertion.

P R O P. XXXV. T H E O R E M.

The parallelograms A, C, D, B, and F, C, D, E, (fig. 27.) constituted on the same base C, D, and between the same parallels A, B, and C, D, are equal to one another.

For the demonstration of this, and the three following propositions, the reader is referred to Euclid.

P R O P. XXXVI. T H E O R E M.

Parallelograms on equal bases, and between the same parallels, are equal.

P R O P. XXXVII. T H E O R E M.

Triangles (being the halves of parallelograms) constituted on the same base, and between the same parallels, are equal.

P R O P. XXXVIII. T H E O R E M.

Triangles on equal bases, and between the same parallels, are equal.

P R O P. XLVI. P R O B L E M.

On a given right line A, D, (fig. 11.) to describe a square. Draw the right line A, G, perpendicular to A, D, make A, B, equal to A, D, through B, draw a parallel to A, D, and through D, draw a parallel to A, B.

P R O P. XLVII. T H E O R E M.

In any right-angled triangle, (fig. 28.) the square of the hypotenuse, (*i. e.*) the side opposite to the right angle, is equal to both the squares of the other sides taken together.

For demonstration, the reader is referred to *Euclid*; but to assist the imagination, a regular figure is here exhibited, which will make the proposition evident, on inspection only.

P R O P. XXXI. of the third book of *Euclid*. T H E O R E M.

The angle in a semicircle (fig. 6.) is a right angle. For demonstration, see *Euclid*.

D E F I-

D E F I N I T I O N III. B O O K VI.

A right line is said to be cut in mean, and extreme proportion, when the whole is to the greater segment, as the greater segment is to the less.

LEMMA. Fig. 29.

To divide a given line A, B, in extreme and mean proportion.

Through the extremity A, draw F, D, perpendicular to it, bisect A, B, in X, take A, D, equal to A, X, and from D, as a center, with the radius D, B, describe the arc B, F; then from A, as a center, with the radius A, F, describe the arc F, C, and C, will be the point sought. *Euclid*, Prop. XI. of the second book.

P R O P. II. B O O K VI. T H E O R E M.

If a right line a , c , be drawn parallel to one of the sides A, C, of a triangle A, B, C, (fig. 9.) it shall cut the sides of the triangle proportionally. See *Euclid*.

T H E
P R A C T I C E
O F
P E R S P E C T I V E, &c.

THIS treatise, being chiefly intended for those who are versed in *Designing*, begins immediately with the practice of perspective; though the utmost care has been taken to render every thing as clear, to any attentive reader, as the nature of the subject will admit. With this view, as many of the known terms are preserved, as possible, that all may be readily understood by those to whom these terms are familiar; though others might have been invented that would have been preferred as more significant, if the author had intended to exhibit a theoretic system.

His aim is to render the practice intelligible and easy, to such as above mentioned; for whose sake, the terms and methods in common use are employed, so far as is consistent with the improvement proposed; and in those cases where others become necessary, they are introduced and explained, and not before; by which means they will be more readily understood, and more easily remembered.

The reader is supposed to be acquainted with some of the first elements of Geometry, otherwise he wants the very language of the science.

The letter S, is every where used for the point commonly called *The point of sight*, which is the same point that Dr. Taylor (more properly) calls *The center of the picture*, it being *that* wherein the picture is intersected by a right line from the eye of the spectator, perpendicular to the picture (or to its plane continued, if need be) which line is the distance of the picture; and that end of it, supposed to be at the eye of the spectator, is always marked D, whether placed on the horizontal line, or elsewhere, and is called *The point of distance*.

The point S, may very properly be considered as the center of the picture, for if a circle be described round it, with a radius equal to the distance, the point D, may be placed any where in the circumference of that circle.

Fig. 1. S, d, is *the horizontal line*, or *vanishing line* of the horizontal plane, it being the intersection (with the picture) of a plane passing from the eye, parallel to the horizon. S, *the point of sight*, or *center of the picture*. D, *the point of distance*; as are also d, and D, (in the circumference of the same circle.) G, H, is the *ground line*, or intersection (with the picture) of an original plane, *which is here* the plane of the horizon. A, is an original point, on that plane, supposed to be beyond the picture, so far as it is placed below the *ground line*, that is, from A, to a; and therefore (once for all) it may be proper to remark, that whatever is so situated, should be conceived to be turned back, behind the *ground line*, and D, to be turned forwards, on the point S, in such manner, that A, a, and D, S, be parallel to each other, and (in the present case) both perpendicular to the picture; then supposing the picture transparent, the point A, will be seen through it at a, by an eye placed at D; or, to explain it otherwise, the visual ray from D, to A, (when in the situation above) will intersect the picture in a. For suppose a plane passing through the lines D, S, and A, a,) when both are perpendicular to the picture) that plane will cut the picture in the line S, a. Now the point a, must be somewhere in the visual ray, D, A, and it must also be somewhere in the line S, a; therefore it must be in their intersection a, the only point

point common to both lines. And the same line S, a, would be the intersection of a plane passing through D, S, and A, a, though these two lines were not perpendicular, but in any other direction (*not parallel to the picture*) provided they were still parallel to each other; and therefore the same point a, will be as truly found in whatsoever direction A, a, and D, S, are drawn, if still parallel to each other, as here A, is transposed to *A*, on the *ground line*, and D, to d, on the *horizontal line*; then drawing d, *A*, and a, S, intersecting it in *a*, that will be the same perspective representation of A.

It is evident also that a, a, is the *perspective* of a, A, (an original line) and the whole line a, S, is the *perspective* of the same original, continued infinitely, of which a, a, is a limited part, and all lines terminating in S, represent originals perpendicular to the picture; for S, represents a point infinitely distant, to which all such lines tend, or (which is the same thing in perspective) seem to tend; and is called their *vanishing point*. Hence it appears, that the perspective representation of every original right line, *not parallel to the picture*, is included between its *intersection* with the picture, and its *vanishing point*:—that is, having continued that original line (*whether perpendicular, or oblique*) till it cuts the picture, as here in a, and having drawn a parallel to the original line, from the eye, cutting the picture, as here in S, the line drawn from a, the *intersection*, to S, *the vanishing point*, will be the whole representation of the original line; though that line be infinitely continued beyond the picture. The representation of the more distant parts of which will approach to S; but the most distant point, short of infinite, will not reach S; therefore that is very properly named the *vanishing point* of such line.

A, is here transposed to *A*, and a, *A*, becomes by that means parallel to S, d; it is so transposed, because in this, and most cases, it is easiest for the operation; but though it is necessary that these two

lines should be parallel, yet they may be *so* in any direction ; for suppose D , transposed to D , and A , to j , the visual ray, D, j , will cut a, S , in the same point a , as is evident.

It is recommended to those readers who have not yet begun this study, to re-consider what has been said, till they fully conceive every part of it, before they proceed ; and if they draw the schemes themselves, they will apprehend the reasons of the several operations much better, and even save time by so doing.

In like manner may be found the *perspectives* of any number of points, and consequently of lines, and superficies : for instance,

Fig. 2. C, B , is a line in the same original plane (whose intersection e , is found by continuing it to the ground line) the extremities of which, being points, are set off, (in the same manner as was A) on the ground line, to f and g ; from each of which, by drawing a line to d , and then drawing e, S , are found the points c , and b , the perspectives of C , and B , and thus c, b , is the *perspective* of the original line, C, B .

Fig. 3. E, F , is a line lying oblique to the *ground line*, whose *perspective* is found in the same manner, *viz.* by drawing perpendiculars from E , and F , to the *ground line*, and from each intersection drawing a line to S ; then transferring the distances of E , and F , to the same line, and thence severally drawing to d , cutting the two lines (tending to S ,) in e , and f , and drawing e, f , this line becomes the *perspective* of the original line, E, F .

Thus any right line, however situated, may be represented, by finding the *perspective* of its two extremities. Hereafter a shorter, and better method will be shewn of projecting any oblique lines, but it was necessary to begin with points.

Fig. 4, 5, 6, 7. It is obvious, that the perspective representations of the square, and parallelograms are found the same way, and that the reason why the square needs no pricked arch, is, that having all its sides equal, the diagonal from d^2 , determines the perspective depth, without any farther trouble.

Fig. 8. And for the same reason, the easiest way of describing the perspective of a circle, is by including it in a square, and finding the eight points marked 1, 2, 3, 4, 5, 6, 7, 8.

Fig. 9. The perspective of any irregular plan, as A, B, C, &c. may be found by the several points, as is evident. It is to be remarked, that the pricked arches by which the distances are set off to the ground line, should always be on the side opposite to d, (*i. e.*) when d, is to the right of S, they should be transferred to the left, and so *vice versa*.

Fig. 10. When a square is placed touching the ground line, in one point, so as to make, with that line, an angle of 45 degrees on each hand, continue the sides, as A, B, and A, C, to the *ground line*, and draw from the points b, and E, to d¹, and from the points c, and E, to d², which will give the *perspective*; (d¹, and d², being equally distant from S.) But in the second part, an universal rule will be given for all situations of original figures.

S O L I D S.

Fig. 11, 12. **T**H E plans are first reduced to perspective, as here of the cube, and parallelopiped, by the rules above, then perpendiculars raised on the ground line equal to their true, or geometrical heights, and from the tops, lines drawn to S; then other perpendiculars from the remaining angles of the perspective plan (meeting the lines drawn to S, from the first perpendiculars) complete the solids.

Fig. 13. This figure is a Tuscan pedestal, whose geometrical plan, and elevation, are first described, then the plan in perspective, which may be either in its place, on the picture, or (as here,) below it, this being chosen that it may not incumber the work above, and also that it may be more distinct, by being less crowded in space. This is performed as the square at Fig. 4, and the inner squares are determined by the diagonals, crossing the rays drawn to S, from the lowest line taken from

the geometrical plan with its divisions. After this operation, continue the several parallel lines of the geometrical elevation, to the line of section F, G, by pricked lines, and from all those interfections draw to S: Then set off from G, on the ground line, the divisions of the geometrical *plan*, taken from the base of the pedestal, (*viz.* 1, 2, 3, 4—5, 6, 7, 8,) and from these divisions draw lines to d, which lines will cut the line G, S: from which interfections, raise perpendiculars to the respective members of the pedestal; these perpendiculars will complete the perspective elevation marked E.

The perspective plan might have been made nearer to S, or any where on, or below the ground line, beyond the numbers 1, 2,-----8, so as not to interfere with them, or on the other side of S, (*e. g.*) as far as Fig. 14; for the perspective elevation E, would have served for *that*, by means of parallels.

Then the whole is completed, by raising perpendiculars from the several angles of the perspective plan, and cutting them by parallels from the corresponding angles of the perspective elevation; and lastly, by tracing the figure thro' these interfections; as for instance, a perpendicular from 9, in the perspective plan, Fig. 13, and a parallel from 9, in the perspective elevation, will meet at 9, in the finished pedestal, and so of the rest.

N. B. When the perspective plan is, at once, represented in its proper place, (*i. e.*) on or above the ground line, as at No. 14. then parallels drawn from the several members of that plan, will cut the lowest line G, 9, of the perspective elevation E, in the true points, from which the perpendiculars are to be raised to complete that elevation; but when it is found more expedient to make the plan below the ground line (as at No. 13.) it is necessary to set off the geometrical breadth of the plan from G, on the ground line, with its divisions, which must be then drawn to d, as before directed, and thereby the perspective figure completed; for perpendiculars from this last perspective plan, tho' below the ground line, will meet the parallels from the perspective elevation in the same points.

These

These several ways are explained, that the principles may be more clearly understood ; but the best of all methods to conceive them thoroughly, will be to perform these operations at the time of reading, and not to pass on to another figure, till all the former are fully comprehended : it is also recommended to such as are not practised in the art, to perform this Fig. 13, in the several ways mentioned, before they read farther : they will then proceed with more facility and pleasure.

Fig. 14. This figure is projected in the same manner as the last, except that, instead of the plan and elevation drawn geometrically, the breadths only of the plan, and heights of the elevation, are marked with their several divisions ; all which are drawn to S , and a diagonal from d^2 , gives the squares of the plan ; then from the several divisions of this perspective plan, parallels are drawn to the lowest line of this substituted elevation, and from these interfections, perpendiculars to the heights of the several members : By means of this preparation, the whole is completed in its place ; tho', as hath been said, the plan, and line of elevation, may be separated, to avoid confusion.

Fig. 15. This example is of a rough pedestal without mouldings.

After having made the geometrical elevation and plan, draw from every angle of both to S , thro' the line d, A , which is to be considered as the section of the picture ; with this distinction, that d, G , part of it, is the perpendicular edge of the picture, and consequently will determine the heights of all the points, by means of parallels to the horizontal line, drawn from the interfections of the rays, as 1, 2, 3, &c. but from b , to A , (inclusive) the interfections are supposed to be on the bottom of the picture touching the ground ; and are therefore to be transposed to G, H , the ground line, as at $h, g, G, \&c.$ — a , representing A ; for setting one foot of your compasses at A , and extending the other to h , on the line of section, the whole is transferred to the ground line, from a , to h , together with the intermediate divisions, from which last points, perpendiculars being drawn, will meet the respective parallels in the true perspective points, which being joined will form the figure.

N. B. In the ground line, the point *h*, must be placed exactly at the same distance from *f*, as *h*, is from *d*, on the line of section ; otherwise the pedestal will not be seen in the picture, as the spectator standing at *S*, sees the original. *This method of projection is Pozzo's, in his second volume, and is introduced for reasons which will be explained hereafter.*

Fig. 16. The next is without geometrical plan, or geometrical elevation.-- Having first drawn the base line, *a, b*, and divided it geometrically at *c*, and *d*, (for the body or trunc of the pedestal) project the whole base perspective, by means of a diagonal from *D*, then any where apart on the ground line, as at *k*, erect a perpendicular, the height of the whole pedestal, and divide it geometrically at the heights of the several members ; and from these divisions draw to any point in the horizon, as *f*: after which, draw parallels from all the angles of the perspective plan to *k, f*, (the lowest line of the perspective elevation,) and, from these intersections, erect perpendiculars, cutting the several lines drawn to *f*, and, by these last intersections, form the perspective elevation, then, by means of parallels, from the several members (cutting perpendiculars, raised from the several angles of the perspective plan) complete the figure.

Fig. 17. Here is added one object more, lest any difficulty should arise from such figures whose sides are not similar, but whoever has understood thus far, will perceive how this is performed on inspection ; the method being the same as at Fig. 15, except that instead of drawing all the lines of the geometrical* to the point *S*, in the horizontal line. In this scheme, those of the plan are drawn to another point below, as *T*, to avoid confusion, but then it must be remarked, that as *T, f*, is equal to *S, D*, (the distance) so *R, b*, must be equal to *f, B*, for the reason given above at Fig. 15, and here the line of divisions taken from *1 B, &c.* transposed to *1 b*, was set off on the ground line, the contrary way to that of Fig. 15, (the rays being drawn to *T*, the contrary way to *S*,) that the rays in the finished figure may run to *S*².

* The term *geometrical* here, and elsewhere, (when without a substantive) is used substantively for the original object, as the term *perspective* is frequently used for the representation.

Fig. 12.

Fig. 11.

Fig. 10.

Fig. 14.

Fig. 13.

Fig. 18. Is performed in the same manner as 14, but in this, the lines which form the perspective plan, are left visible, that the operation may more easily be understood. The measures for the perspective plan are taken from the geometrical, and set off on o, p . From thence rays are drawn to S^3 , and the diagonal from p , to D^3 , cuts the ray q, S^3 , in the point z , which determines the perspective square, that represents the square B, Z , in the geometrical plan, and, by means of this, the whole plan is put into perspective. On the perpendicular $o, 7$, mark the geometrical heights of the several members, and from these divisions draw rays to S^3 , and then draw parallels from all the angles of the base, to o, S^3 , the lowest ray; and from the several intersections, raise perpendiculars to the uppermost, and so form the perspective elevation, as at Fig. 14, *but which is more apparent at Fig. 16, because the elevation is there separated from the body of the pedestal, tho' the method is the same*). Now raise perpendiculars from all the angles of the plan, and, by means of parallels from all the members of the elevation, meeting these perpendiculars, complete the whole figure, in the same manner as was done at Fig. 14, and 16.—*Particular care must be taken that each parallel, from the elevation, meet its correspondent perpendicular from the plan, to determine the same member, and this is, perhaps, the easiest, and shortest method of all: for the perspective plan is made with as few lines, and in as little time as the geometrical, which is unnecessary here; and instead of the whole geometrical elevation, the geometrical divisions, or heights only (on the first line $o, 7$) are necessary: so that the measures may be taken from a book of architecture, without drawing any thing geometrically; and if their measures (in such book) be on a larger, or smaller scale, it is easy to set them off in any proportion required for the perspective; as in this very figure, the measure for the base is limited to o, p , wherefore first draw o, p , in its place; but as the measures here, are equal to the original at B , and this expedient (for that reason) unnecessary in the present figure, it is more convenient to shew it apart.*—Suppose then, o, p , drawn in its place Fig. 18. (as directed above) draw from o , any other line, o, t , and on it mark all the geometrical divisions of the plan from the book; then lay a parallel ruler from

C

t, to

t, to p, drawing t, p, and parallel to it, all the rest of the divisions from o, t, to o, p, and the line o, p, will thus be truly divided; whether o, t, be longer or shorter than o, p.

And also having drawn in its place a perpendicular to o, p, as o, 7, for the elevation, draw any other line from o, as o, r, on which mark the divisions of the geometrical elevations from the same piece of architecture in the book, and (in order to preserve the proportion of the base) set off the measure of o, p, on the perpendicular o, 7, reaching to v, and the measure of o, t, on o, r, reaching to t², then lay the ruler from v, to t², drawing that line, parallel to it, transfer all the divisions from o, r, to o, v, which will give them in the same proportion as those on o, p.

In this first part, the several methods proposed by writers before Dr. *Taylor* are exhibited, any of which will answer the purpose, when objects are placed directly in front, and on the horizontal plane; but when objects are in an oblique situation, even on the horizontal plane, and especially when they are on an oblique plane, or when the figures to be represented on any plane are themselves irregular, the new method will appear preferable beyond all comparison.

S E C O N D P A R T.

THESSE few examples are sufficient for the first part, that being intended only to exhibit the common methods, with some improvements; which methods, tho' useful in many cases, are no more proper for some, than the rule of addition, in arithmetic, is proper for finding the product of a sum in multiplication; and notwithstanding a person, ignorant of multiplication, might find, by addition, how much 300 times 278 makes; yet, in order to ascertain it, he must set down 278 three hundred times, and add all together; whereas, if he understood multiplication, he would do it in an instant, and be much less liable to mistake: It is not pretended that the cases are exactly parallel, but a few examples will shew that this may not improperly serve

Fig. 16.

Fig. 25.

Fig. 27.

Fig. 28.

for illustration, and that the common methods are attended with such tedious operations, such a multitude of unnecessary lines, and, in some situations, with such perplexed and intricate schemes, as require more than human patience to execute, and, after all, render mistakes almost unavoidable, of which any one will be convinced who shall examine the plates of *Pozzo*, even in his second volume, where he has published his shorter method, which he had promised in his first, as well as in other authors; especially when they exhibit objects in oblique positions, not only on oblique planes, but even on that of the horizon.

In this second part, therefore, it is proposed to shew the advantages of the new method, by comparing it with the old, in several instances: and here it may be proper to observe, that those readers, whose leisure or curiosity may not permit, or incline them to examine the several comparisons proposed, may neglect the examples of the old methods, and go regularly thro' those of the new, and so arrive at the knowledge of the practice the shortest way at once: those however who are already acquainted with the old methods, will be better satisfied on seeing the different manners of operation, in the same examples; and it is presumed that much the greater number of readers may be of this class.

Fig. 19. A, B, C, E, a parallelogram, making a given angle with the ground line G, H, represented, in perspective, by the common method before explained.

Fig. 20. The same parallelogram by the new method. And here, instead of placing the distance on the horizontal line, it is proper to raise it perpendicularly, as S, D; then continue the sides of the plan C, A, and C, E, till they cut the ground line in G, and H; from D, draw D, a, parallel to A, B, and C, H, cutting the horizontal line in a, and draw D, e, parallel to E, B, and C, G, cutting the horizontal line in e; then draw B, a, and H, a, and also B, e, and G, e, which complete the perspective representation: the lines themselves forming the figure, without the trouble of finding points, or risque of mistake, or of inaccuracy in joining them when found.

N. B. A, B, and C, E, H, being parallel, D, a, is parallel to both; as is D, e, to E, B, and C, A, G; and it is an universal rule, that all original lines parallel to each other, (and not parallel to the picture) run to the same point in perspective; which, when not the point of sight, is called by the old writers an accidental point, or more generally a point of concurrence; but by *Taylor*, a *vanishing point*, whether it lies in the horizontal line, or elsewhere: Thus a, is the vanishing point of A, B, and C, H, and B, and H, being their interfections, their perspectives are found between B, and a, and between H, and a; and so, universally, the perspectives of all original lines (not parallel to the picture) lie between their interfections with the picture, and their vanishing points, as was observed before.

Fig. 21. A, B, C, E, the plan of a cube placed obliquely to the ground line.--It is required to find the perspective of the whole cube in that situation.

According to the old method: After having found the perspective of the plan, and raised perpendiculars from all the angles, set off the geometrical height any where on the ground line, as at *f*, and draw from the extremities *f*, and *g*, to any point in the horizontal line *h*; then draw parallels from all the angles of the perspective plan, to the lower line *f, b*; and, from the interfections, raise perpendiculars to the upper line; and then, from these perpendiculars, draw back other parallels to the corresponding perpendiculars raised from the angles of the perspective plan, which will complete the cube.

Fig. 22. To represent the same according to the new method: After having found the perspective plan, (as at No. 20.) raise perpendiculars from all the angles of the perspective plan, and make *c, 1*, (which touches the ground line) of the true geometrical height; then from *1*, the top of this line, draw to *e*, and *k*, (as before for the plan,) and from *2*, to *K*, and from *3*, to *e*, interfecting each other at *4*, and so finish the upper square, as the lower, which completes the figure.

After

After what has been said (at Fig. 15. and 17.) of *Pozzo's* second method, it would not be necessary here to add any thing more in explanation of it, if it were not, that there will be several occasions for the same kind of operation ; wherefore, to render it as clear as possible, the following example is proposed.

Fig. 23. A, is an original parallelogram, supposed to be placed on the horizontal plane, behind the picture, whose intersection with that plane is G, h, the spectator standing at d ; wherefore first draw lines from each angle to d, which will cut G, h, then transfer those intersections to the proper ground line of the picture G, H ; begin by setting one foot of the compasses in o, (which is the intersection of d, o, with G, h, perpendicular to it,) and so transfer the several divisions from the line G, h, to the line G, H, beginning at O, in this last line ; and from 1, 2, 3, 4, on G, H, raise perpendiculars.

After this operation, raise perpendiculars also from all the points of the original figure A, to the line G, H, (continued behind G,) and from their intersections with this line, draw lines to S, which will cut G, D, the section (or upright edge) of the picture, and from these intersections (*viz.* of the lines to S, with G, D,) draw parallels, which meeting with the perpendiculars raised from 1, 2, 3, 4, determine all the points of the perspective ; but here care must be taken that each parallel determines its corresponding perpendicular ; as for instance, the perpendicular 3, corresponds with the lowest parallel, marked also 3, and their intersection represents the nearest point of the object marked 3, and so of the rest, which are all marked with their corresponding numerical figures : this, and the examples before referred to, are performed by the shorter method of *Pozzo*, exhibited in his second volume, which he proposed as the most expeditious manner of all ; and for that reason it has been thought proper here, and in some following examples, to make the comparison between this method and the new.

This example is the same kind of object, and situation, as is above shewn at Fig. 19, in the common method, and Fig. 20, in the

the

the new, to which the reader is referred, who may compare them together.

Here is also added the same object, according to the method of *A. Boffe*, (a famous French engraver and author, who wrote about one hundred years ago) not only because he asserts his to be the easiest, shortest, and most exact of any to that time, or that ever could be invented *, but also because it is still so esteemed by some moderns ; he proposes two methods little different from each other, both of them are shewn in this example.

Fig. 24. And first at Fig. 24, where the original object is enclosed in squares of feet (or any known measure) geometrically, the distance is set off in the same measure, as from *p*, to *D*, eight feet, and the height of the eye, as from *D*, to *O*, five feet.

In order to put this in perspective, as below at Fig. 25, draw the ground line *G, H*, and divide it into feet ; draw *S, S*, for the horizontal line, parallel to *G, H*, and the height of *D, O*, from it ; and having placed *S*, on that line perpendicularly over *P*, (which corresponds with *P*, above,) draw rays from all the divisions to *S* ; then, in order to reduce the squares into perspective, (instead of setting off the distance from *S*,) make a perspective scale, or *echelle fuyante*, (as he calls it,) by marking from any point of the horizontal line eight parts of any opening of the compasses for the eight feet : as here from *a*, to *b*, and take one of these parts from *G*, to *d*, draw *d, a*, and *G, b*, which will cut *d, a*, in *c*, draw the parallel through *c*, and from the point where that cuts *G, a*, as at *e*, draw again to *b*, and so on, till you have as many parallels as are wanted. *G, a, d*, is what he calls the scale, the peculiar advantage of which is, that you may always divide the squares perspectively within the picture, whatsoever distance be taken, because any opening of the compasses may answer to your foot, the truth of

* *His words are*,—laquelle maniere s'est treuvée, sans contredit, la plus familiere, et abregée, juste, & precise qu'aucune qui ait encore parue, et j'ose bien dire qui paretra. *Avertissement.*

His book is intitled, "Moyen universel de Pratiquer la Perspective sur les Tableaux ou Surfaces irregulieres, &c. A Paris, MDCLIII. Par A. Boffe."

And again Chap. I. J'ay dit que j'avois mis en lumiere un traité de perspective que je crois, avec plusieurs, estre le meilleur qui se soit fait, et, se fera, &c.

Fig. 22.

Fig. 21.

Fig. 23.

the operation depends only on making G, d , equal to one such opening, or division. Now find the several points, of the object in these perspective squares, corresponding to the original in the geometrical plan, join these points, which complete the work.

His other manner differs in nothing from this, except that instead of drawing the rays and the parallels quite through them. You need only make the perspective scale, and divide the perpendicular S, P , by that scale, and so measure the depths of the several points by the line S, P , and the breadths from the same line on both sides, corresponding to the original: but then, in order to set off the parallel feet, it is necessary to add the line e, a , placing e , one real geometrical foot distant from G , which will determine the perspective parallel feet, all the way up.

The performance of all these particulars will convince any one of the tediousness, as well as uncertainty, of this manner of working; it will be found almost impossible to ascertain the exact place of the several points, even with the utmost care; not to mention the necessity of making all that preparatory geometrical work, if not in squares, yet in divisions*.

Fig. 26. Next follows the same object, according to the new method, in order to be compared with those above, which having been before explained at Fig. 20, from which this differs only, in that the nearest angle touches not the ground line. It is to be observed, that the lines here form the object, without the possibility of mistaking, and with the utmost exactness, and in the tenth part of the time. The perpendicular S, D , is the distance o , and d , the two vanishing points, found by drawing D, o , on one side, and D, d , on the other side parallel to A, B , and E, B , respectively.

Fig. 27. This pedestal is represented in perspective by *Pozzo's* shorter method, as explained at Figures 15, and 17, to which nothing need be added, except that the geometrical elevation must be formed by

* To do justice, however, to the author, it is acknowledged that this scale is, in some cases, a very useful expedient; though it will by no means justify what he says of his general method.

perpendiculars from all the angles of the plan; as placed obliquely, which, in a complicated design, makes sometimes a very odd, and intricate figure, scarcely intelligible, as appears in several instances in *Pozzo's* second volume; whereas, according to the new method, this never happens; but, on the contrary, how complicated soever the original may be, the plans and elevations always make the same kind of figures as the original geometrical objects. This will be shewn hereafter.

The operation is the same as at Figure 23. And here, besides the great number of lines, much time, patience, and care, are necessary to find the corresponding points, (after having drawn all the perpendiculars, and parallels of the plan, and elevation,) which renders the work very liable to errors.

Fig. 28. Here is also added the same pedestal, in the same position, according to *A. Bossé's* method, by means of squares, (which is shorter than his other mentioned before, because the measuring is avoided, which requires more time than making the squares;) but, besides so many needless lines, there is great danger of mistaking the points by the perspective measures, and much time is necessary to complete the figure with any exactness.

N. B. The small plan above is, (in this method,) a necessary preparation, and the several points of the perspective plan are determined by marking them in the same parts of the perspective squares below, as in this, respectively. The perpendicular *e, f*, on the side of the small plan above, is divided geometrically for the height of the members, which are to be transferred also to the perspective; for instance, the top of the capital is four feet; therefore, on the ground line take four feet, and with that measure turn the compasses from the nearest angle *l*, which touches the same ground line, to *h*.—Again, for the same height at *i*, take four feet on the parallel at *i*, and turn the compasses up to *k*; and so for every other point; after which they must all be joined.

Fig. 26.

Fig. 27.

Fig. 28.

Fig. 29. But in the representation of the same pedestal, by the new method, the whole work is performed by means of three points only, a, b, and c, to which all the lines are drawn, and these lines form the figure itself; so that having fixed one end of the ruler at a, the lines of two sides, (*i. e.*) all that are parallel in the original, are drawn without taking it off, and by placing it at c, the lines of the other two sides are all drawn, without moving the end from thence, and, with the utmost exactness; b is the vanishing point of one of the diagonals, found by drawing D, b, parallel to d, b, in the geometrical plan.

If what has been hitherto said of this method be understood, (especially at Fig. 22.) this will not need farther explanation; however, to leave no difficulty; After having raised perpendiculars from all the inward and outward angles of the perspective plan, the geometrical measures of the heights are marked on the perpendicular of the nearest outward angle, (which is pricked, or dotted;) and, from these divisions, lines drawn to b, cutting the perpendiculars of the nearest and farthest angles of the die, or body of the pedestal, determine the several points of the die; and drawing from these intersections to a, and c, the rest of the die is completed, and so of the mouldings.

Fig. 30. The next figure represents two bases leaning one against the other, taken from the 28th of *Pozzo's* second volume, both of them raised from the horizontal plane; for which reason he says, “*he could not assign a point of sight, and therefore was obliged to transfer all the points one by one with his compasses, that he might find the termination and curvature of each line* *.” And although (in the plate referred to) he has not left the lines by which those points were determined, yet whoever understands his method will perceive the necessity of them, and that in such oblique situations, they must be almost innumerable, as will appear throughout his book, on inspection of the odd plans

* *His words are,*—descendendo cum lineis occultis, ad perpendicularum, ab singulis projecturis limborum describuntur totidem circuli in vestigio, ut unusquisque aptè collocetur, atque ab atrisque fierunt bases opticè adumbratæ: pro quibus certum oculi punctum statuere non potui, eò quod horizontales non sint. Sed transfuli, circino, singillatim, puncta, ut finem, ac sinuationem cujusque lineæ invenirem, &c.

he was obliged to make, which of themselves are extremely difficult to form, and intricate when formed.

The pains of so tedious an operation, as this method requires, might have been spared; but that *Pozzo's* books (especially the second volume) are not in every one's possession; and that, of those who have them, very few (if any) may have given themselves the trouble to project these, or subjects of the same kind, by his rules; and, therefore, may not be sensible of the necessity of using so many lines. It was, therefore, thought expedient to project these bases in his way first.

The manner of working is the same as at Figures 15, 17, 23, and 27, above explained. And first the profiles A, and B, are geometrically drawn, then the plans C, and D, by dropping perpendiculars from every point of the profiles, and from the several points of the axes A, E, and B, F, (which cut the members of the bases) in order to find the several centers on the line C, D, which line receives all the transverse diameters, as *f*, *d*, and its parallels of the base A, and likewise those of the base B; but the perpendicular diameters are transferred from the profiles geometrically, thus; C, represents the center A; *d*, represents the point *d*; and *f*, the point *f*; all three found by the perpendiculars; then from C, upwards and downwards, the geometrical length A, *d*, or A, *f*, is set off from C, both ways, to *h*, and *g*, for the perpendicular diameter *g*, *h*, which completes this circle; the same operation forms each circle, &c. After the profiles and plans are completed, lines must be drawn from every point of both to O, cutting the line 1, 5, part of which, *viz.* from 1, to 3, represents the intersection of the bottom of the picture with the ground, and must be transferred, with all its divisions, to the proper ground line of the picture, and perpendiculars raised from all these divisions. Another part of 1, 5, *viz.* from 4, to 5, represents the perpendicular, or upright section of the picture; and, therefore, from all its divisions, parallels must be drawn, meeting the perpendiculars raised from the divisions of the ground line, and these intersecting, will determine the points of the perspective; but the number and confusion of lines is so great, that it will be necessary to fix every point with the compasses, or (as *Pozzo* himself advises) with a pair

a pair in each hand, as thus ; place one foot of your compasses in 1, on the line of section, and extend the other to 6, which is the intersection of the visual ray from D, to O, and transpose this measure to the picture, setting one foot there in 1, and the other foot will rest on the perpendicular marked 6, in which the center D, is to be found : at the same time, set one foot of the other pair of compasses in 2, on the line of section, and extend the other to the point where the ray B, O, cuts that line, as at 7, and transfer that height to the perpendicular 6, on the ground line, (found by the other compasses,) which will mark 7, on that perpendicular, the perspective of the center sought ; and this double operation must be repeated for every point, till all the points in the perspective are found, which must afterwards be joined : in doing all this, great care must be used not to mistake ; and when completed, can never be so true as by the other method ; because here the several lines, which should be drawn to the same vanishing point, must be drawn from point to point only. Here are used five points only for each circle, *viz.* the center, and extremities of two diameters, to avoid adding more lines.

As to the parallels and perpendiculars, which inclose the perspective, they might have been omitted, if the two pair of compasses be made use of ; and especially if the person using them has got into the habit : but these lines are left, that every thing may be clearly understood ; but as the parallels are in themselves necessary to mark the line of section, they are only continued on to the bases, and do not increase the number of lines.

All the other lines are absolutely necessary in *Pozzo's* second, or shorter method. The great number of lines, and the confusion arising from thence, has caused even him to mistake, the lower base being false in his plate ; for the lines representing the thickness of the plinth, which are perpendicular to the ground line, and parallel to each other, ought to run towards a certain point, and so be neither perpendicular, nor parallel : if the fault be not his, it may be the engraver's ; but whosoever it be, the print is apparently wrong.

Fig. 31. In order to represent this according to the new method, it was necessary to find the centers and distance, both of the vanishing line, and picture, by continuing the two sides of the lower plinth till they met in a point, (as here in C,) and then drawing C, D, parallel to the ground line: Thus, C, D, becomes the vanishing line of the oblique plane, which the lower base forms by being raised, and C, its center.

N. B. *This line is always to be used for objects obliquely situated, as the horizontal line is used for objects on that plane.*

The point of distance D, of this vanishing line, was also found, by drawing a line through the diagonal of the square of this plinth, from the angle 3, to the vanishing line C, D. Thus far, from Pozzo's book, for otherwise, these are circumstances always given.

These points being found, half the measure of Pozzo's was taken, and so the same proportions were preserved.

The rest is all performed as before explained; but the situation of the objects being new, a more particular detail may be useful, and will shew the universality of the principles.

As the center of the picture, found, by a line, perpendicular to it, from the spectator's eye, is that point to which all original lines, perpendicular to the picture, tend; so every vanishing point being found by some line from the eye of the spectator to the picture, is also the vanishing point of all other lines parallel to that; and every line from the spectator's eye cutting the picture, (or plane of the picture how far soever extended,) makes such a vanishing point; thus C is the vanishing point of the line 1, 2, and of all original lines parallel to it.

S, D, is the horizontal line, found by making the angle D, C, D, equal to that which the plinth makes with the ground, and describing an arc from D, to D, with an opening of the compasses, or radius, equal to C, D, (the distance before found,) and drawing D, S, parallel to D, C; then drawing through C, a line perpendicular to D, C, cutting D, S, in S, that point S, becomes the center of the picture, and D, S, the distance of it.—D, C, is the distance of the vanishing point

Fig. 30.

point C, and of the vanishing line D, C ; and D , is to be considered as the eye of the spectator; therefore (if D, C , finds the vanishing point C ,) a line from D , perpendicular to D, C , must find the vanishing point of lines perpendicular to 1, 2, as D, d , finds d , cutting C, S, b , beyond the limits of the paper, which will be the vanishing point of the line 1, 3, and all others parallel to it, as are those at all the angles of this plinth, which must therefore be drawn to d , as the line D, d , cuts the line C, S , beyond the limits of the picture; but it is not necessary to stop here to explain the manner of drawing lines to an inaccessible point, (which is done in the fourth part :) then, for the thickness of this plinth, draw a line through 1, parallel to C, S , (which is the vanishing line of the planes 1, 2, 3, and 4, 5, 7,) for that point 1, is supposed to touch the picture, (where all objects are of their true, or geometrical size,) and on that line, from 1, downwards, mark the geometrical thickness of the plinth, and having transposed the distance of the vanishing point d , from D , to dd , draw a line from dd , to the point marked, which will cut 1, d , in the point 3; this determines the thickness of the plinth, by which it may be completed. The rest of the members are determined exactly in the same manner, as if the base was on the horizontal plane, using C, D , the vanishing line, as an horizontal line.—The heights, and breadths of the circles are determined in squares, as hath been taught in the first part, and the circles drawn through the eight points there specified.

For the other base, draw first the pricked line 3, S , which marks the ground or horizontal plane, perpendicularly under 3, k, C ; then set off from 3, to f , the geometrical distance, that the angle of the other plinth is from the point 3, and from D , draw a line to f , cutting $S, 3$, in 4, and that intersection will be the point sought, in which this plinth touches the ground; and having drawn D, b , making the angle S, D, b , equal to that which this plinth makes with the ground, (*i. e.*) 38 degrees, b , is the vanishing point of the line 4, 5, and its parallels; therefore draw $b, 4, 5$; then to find the length of that line, make use of the parallel to the vanishing line C, S , before drawn, *viz.* 1, 3, e ,
by

by drawing first a line from db , (the distance of D , b ,) through 4, to that line, cutting it in e ; and from e , upwards, mark the geometrical length to g , and from g , draw back again to db , which gives the perspective length of 4, 5; from which points 4, and 5, parallels to the ground line are drawn; and the length of the parallel at 4, is found by drawing a line from S , to the point 6, cutting that parallel, and drawing a line from b , through this last intersection, it will cut the parallel 5, 8, in 8, and so complete the bottom, or lower square of the plinth.

Or this square may be determined (without making use of the line 1, 3, e ,) by first finding the length of the parallel at 4, as last directed, and then drawing a line through the intersection which marks that length, from D^2 , (the distance of the vanishing point b ,) to the line b , 4, cutting it in 5. This line D^2 , 5, gives the diagonal of the square, by which it may be completed.

N. B. The distance b , D^2 , is brought down to D^2 , by fixing one foot of the compasses in b , and the other in D , and describing an arc, till b , D^2 , is parallel to the ground line; and so it becomes the vanishing line of the plane, or square of this base.

D , a , being drawn perpendicular to D , b , finds a , the vanishing point of 4, 7, and its parallels; wherefore draw from 4, 5, and 8, to a , and having found the perspective height of any one of them, by the same operation as for the other plinth, this is completed. And to find that height, draw a parallel to S , C , a , from 4, upwards, and on that mark the proportional height or thickness, which is found by drawing from S , through 4, to 4, the ground line, making another parallel, as 3, 1, there, of the geometrical height, and from 1, the top of that, a line drawn back to the same point, S , will cut the parallel drawn from 4, in the true proportion. Now, from d , a , (the distance of a ,) draw a line to this last intersection, cutting 4, 7, in 7, and from b , through 7, a line cutting 5, a , and from that intersection, a parallel to 5, 8, by which the plinth is completed. The other members are determined, as those of the first base.

Or

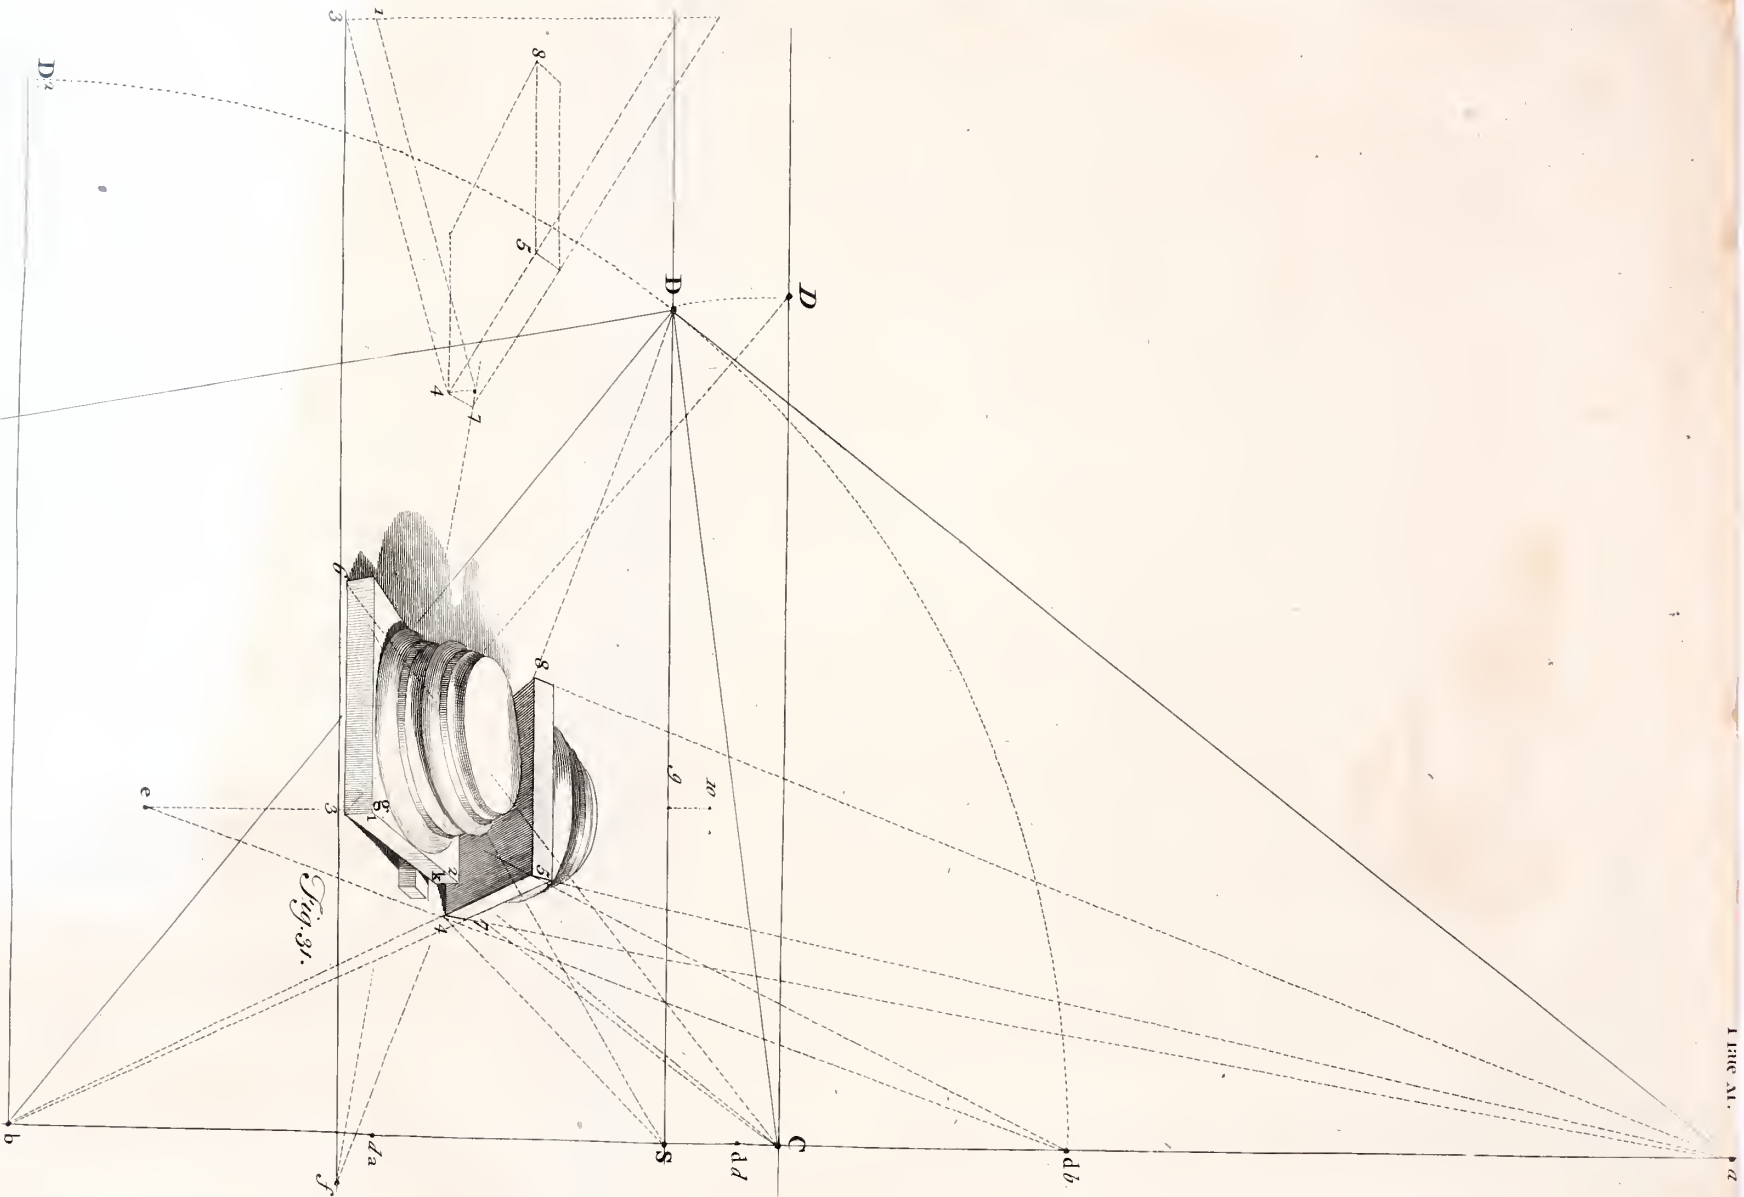

Fig. 31.

Or (omitting the parallel to S, C, a , drawn from 4,) continue the line 3, 1, upwards, and then produce the line $b, 4$, till it cuts that line (3, 1, continued) as at 9, and there mark the true geometrical height 9, 10, and draw $b, 10$, which will cut the line 4, a , in 7, and so finish the base. By this, the trouble of finding the proportional height at 4, is saved.

That the whole operation may be more easily comprehended, it is again represented apart from the picture, in pricked lines, drawn from the same points, and marked by the same numerical figures.

This explanation is lengthened by the necessity of shewing how the scheme was prepared from *Pozzo*, the intention being to represent these bases exactly in the same situation, as he had placed them; for otherwise, (*i. e.* without any reference to him,) the description would have been more simple; it is also very minutely particular, that nothing material might be left unexplained, it having been said at the beginning, that these things should be referred to the occasions that might require them, in order to avoid unnecessary definitions, &c. Though this method is less regular, yet it is much more easy, because the explanation attends the use.

Those who may not readily comprehend every particular, at the first reading, are advised to draw, in perspective, the two plinths only, in these, or the like situations, and to place them at such angles with the ground, that all the vanishing points may fall within the limits of the picture.—By this disposition, they will better see the reason of every operation; and the next figure is added to assist them in it.

Fig. 32. Here the vanishing points are all within the paper, and nothing completed but the two plinths, the lower of which is raised higher from the ground than in the preceding example, not only to bring the vanishing point d , within compass, but also to shew, evidently, that the lines 1, 3, and 6, 9, cannot possibly be perpendiculars to the ground line, nor parallel to each other (as they are in *Pozzo*) when the base does not lie flat on the horizontal plane.

In this scheme 3, 6, touches the ground line ; and is therefore the true geometrical length. C, D, is the vanishing line of the oblique plane, to which the base is raised, or on which it may be supposed to lie. The lower square is therefore projected by means of C, the center of that vanishing line, and D, its distance ; as readily as, if it was on the horizontal plane, it would be, by means of S, and D, the center and distance of that plane.

Now draw from d , (found as in the foregoing example) through 3, and 6 ; then raise a perpendicular from either of them, as here from 6, on which mark the geometrical height, or thickness of the plinth, at e , and having set off the distance d, D , to dd , from thence draw through e , which will cut $d, 6$, in 9 , and $6, 9$, will be the perspective height ; from 9 , draw a parallel which will determine the point 1, and so complete the plinth, by drawing 1, C, and $9, C$, and from d , draw through the other two angles of the lower square, meeting 1, C, and $9, C$. It is needless, here, to repeat what was before said of the other plinth in the last scheme.

The circles which are here barely traced, are done in the manner explained at the beginning, just as if they were on the horizontal plane.

It is apparent how much work is saved by this method ; neither geometrical plan, nor profile are necessary, if the measures are but known ; and if not, the plan and profile, in their common geometrical situation, will answer the purpose of the most oblique positions ; so that a printed book of the several orders may be referred to, without the trouble of drawing the particular parts that may be occasionally wanted.

Fig. 33. A figure in *A. Bossé's* perspective, for the representation of which, he makes use of several schemes. First, that at No. 1, where $m, e, -n, a$, is, by him, designed for the profile of the seat of the object : z, e , is the inclination of the picture : o , the spectator's eye : a , his station, or feet : o, z , the distance : o, a , height of the eye. If (says he) the object be only a plan, as b, c, d , on the geometrical squares at No. 2, find those several points in the corresponding perspective

Fig. 32.

tive squares below at No. 3. (as has been taught before at Figure 25.) But if the object be above the plane of the seat, as the Fig. *f, r, s*, (in the said geometrical squares, No. 2.) then by means of the elevations *b, f,—c, r,—d, s*, perpendicular to the seat *b, c, d*, draw those elevations parallel to *q, u*, and from the ends of them *b, c, d*, drop perpendiculars *b, 1,—c, 2,—d, 6*; and from their other ends *f, r, s*, draw *f, 1,—r, 2,—s, 6*, making (with them) angles *b, f, 1,—c, r, 2,—d, s, 6*, equal to *n, o, a*, above at No. 1, and draw *1, 2,—1, 6,—2, 6*, you will have another seat *1, 2, 6*, and other elevations *f, 1,—r, 2,—s, 6*. Then find below, at No. 3, the perspective *1, 2, 6*, of this other seat, as *B, D, C*, was found, and make the perpendiculars *1, F, 2, R, 6, S*, in proportion to their respective plans; that is, on the perspective chequer take the same measures along the several parallels of *1, 6*, and *2*, as they have above in the geometrical chequer; then join *F, R, F, S, R, S*, by this means you will complete the perspective of *f, r, s*; and, lastly, join *F, B, S, D*, and *R, C*, which finish the whole prism.

Fig. 34. Now, in order to represent the same object in the same situation, nothing more is necessary than to describe, either geometrically, or in words, the form and situation of the object, or to give one side of it, whose form and situation are known, or described, and require the rest; as here, let *E, F*, be given, it is required to represent a triangular prism, whose base is similar to the triangle *D, f, g*, (above this Fig. 34,) and whose height is in proportion to the side *D, f*, of that triangle, and on a picture inclined to the plane of the seat in the angle *o, a, n*, Fig. 33, No. 1. The picture is as *Boffe's*.

Continue *E, F*, Fig. 34, till it cuts the vanishing line [*C, D, Z, X,*] as in *i*, which will be its vanishing point; then from *C*, raise *C, D*, equal to *C, D*, or [*Z, X,*] the distance given; draw *i, D*, and at *D*, make the given triangle *f, D, g*, continue *D, g*, to the vanishing line, which finds *k*, the vanishing point of *E, G*; therefore, draw *k, E*; then in order to find the length *E, G*, which is geometrically equal to *E, F*, bring down the distance *i, D*, to the vanishing line at *d*, draw *E, b*, parallel to the vanishing line, and draw *d, F*, which

E

will

will cut E, b , in b ; then is E, b , the geometrical length sought, which set off from E , to a ; bring down (in like manner) k, D , to e , and draw e, a , which cuts E, k , in G ; then draw G, F , which finishes the base.

And in order to complete the prism in this situation, having described the arc D, d , with the radius C, D , draw C, d , so as to make the angle D, C, d , equal to the inclination of the original plane, with a plane perpendicular to the picture; that is, to the angle z, o, S , (Fig. 33, No. 1;) and cutting the arc D, d , in d , draw d, S , parallel to D, C ; then S , will be the center of the picture, and the angle C, d, S , equal to D, C, d ; draw d, N , perpendicular to C, d , cutting C, S , (continued) in N , below, which will be the vanishing point of lines perpendicular to the original plane; so that drawing from N , through the points G, E , and F , the lines G, H, E, I , and F, K , are got. And to determine their lengths, the distance N, d , is set off on C, S , at N^2 ; and E, l , being made parallel to S, C , and equal to E, b , (the geometrical height) draw N^2, l , which cuts E, I , in I , the length sought; whence drawing to i , and k , the points H , and K , are determined, which, on joining H, K , completes the whole figure.

N. B. Left the reader should not readily conceive the reason of this operation, there are represented on the profile of *Basse's* figure, No. 1, the lines made use of in this; for instance, S , is there the center of the picture (as formerly explained;) and o, S , properly the distance of the picture, e, y , (being parallel to o, S ;) represents the profile of the plane, perpendicular to the picture; and e, h , being the original plane, on which the object is placed, h, e, y , is the angle of inclination of these two planes, equal to z, o, S , in the same scheme, which is supposed to be given for working the problem; and is the same angle as D, C, d , and S, d, C , in the picture, Fig. 34.

Though

Though the work is simple and short, the text may appear somewhat long ; but that is only because the reasons of the operation are taught, and because every particular is explained in the most familiar manner for the sake of learners.

It might have been remarked before, that this method of *Boffe* is exceedingly operose, and very uncertain ; for in order to transpose the several points from the small geometrical chequer to the larger perspective squares, the rays *Z, B, 1, 8*, (Fig. 33.) *Z, D, 6*, and *Z, C, 2*, should be drawn, and these crossed by lines from the point of distance *X*, to find each point, as *Z, 8*, and *X, 7*, are necessary to find the point *1*, only, (the distance *8, 7*, being the geometrical depth or distance of the point *1*, from the ground line ;) unless there were so many squares in the geometrical plan as to cross every point, which would not only be excessively tedious to perform, both there, and in the perspective, (where all must be repeated ;) but the multitude of lines would necessarily produce confusion ; and if the operation be performed without these lines, then the several places of the points in the perspective plan can only be guessed, by inspection of those in the geometrical plan ; and whatever is done by guess must be uncertain. Whereas, in the new method, there is not a line, or point, necessary, more than are here exhibited, and no possibility of mistake, or occasion of uncertainty, because the lines form the figure of themselves.

Fig. 35. In this figure, which is also *Boffe's* own, he proposes to represent the prism *F, S, R, P, O, G*, on a picture, whose profile *z, e*, above, inclines forward, (as the last did backwards :) the profile of the original plane is *n, a, m, e* ; the whole operation is the same as his last, except that the pricked lines in his geometrical plan, on the chequer, which in the former were drawn downwards, are here drawn upwards, on account of the different kind of inclination : the correspondence of the perspective plan with the geometrical, is evident, therefore needs no farther explication.

Only it may be remarked, to what a confused scheme he was reduced, by his limited principles.

Fig. 36. And how simple and easy the other figure appears, which represents the same object, and is performed by exactly the same operation as Fig. 34, with this only difference, that D , N^2 , runs upwards; whereas d , N , in the other, runs downwards, on account of the different inclination of the object at 34, and 36, (N , in 34, and N^2 , in 36, are the vanishing points of lines perpendicular to the original planes of their respective objects;) and that *this* may, if possible, be more easily conceived, the points S , N , and S , N^2 , are marked with the same letters in the geometrical schemes, Fig. 33, No. 1, and Fig. 35, No. 1. It is true *Bosse* confines himself to the compass of his picture, and undertakes to represent all objects by means of lines terminating within it. This is very well, if it be always the shortest, and surest way; but if there are cases which require more room; that is, if some objects can be represented with greater certainty, by taking more space, or on a smaller scale, and can then be transferred by the picture; and all this done in less than a quarter of the time, that would be necessary to produce them by his method; where is the advantage of confining the operation always to the picture? Besides, the scheme formed to be transferred, remains, and may be very useful another time. Though this object, however, might have been represented by an operation within the picture (with the addition of a few more lines,) on the new principles, *as shall be shewn hereafter*. To all which may be added, that this very figure of *Bosse's* is false, though very neatly engraved by his own hand, which must be owing to what was hinted before, *viz.* that his method requires so much guessing, as to make it almost impossible not to fall into some error from thence. And if, to avoid these errors, a greater number of lines still are drawn, in order to ascertain every point, the confusion would be so much increased, that it would itself become a new cause of mistake.

His error is in placing O , higher than P , G , in Fig. 35, as by the pricked lines; and so representing P , O , G , as above the eye, (and seen on the under part) which cannot possibly be, while it is below Z , X , the vanishing line. This will appear on inspecting his own geometrical profile, Fig. 35, No. 1, where, o , z , represents Z , X ,
(Fig.

(Fig. 35, No. 3.) and shews that if P, O, G, was even with that line, it would be reduced to a single line, and must be represented by it; that if it were ever so little under that line, as at 3, 4, (Fig. 35, No. 1.) then 4 would be seen (by the eye at o) higher on the picture z, e, than 3, which is nearer; and lastly, that if it was above the line Z, X, Fig. 35, No. 3. (and not otherwise) the object would be seen as 1, 2, Fig. 35, No. 1. (*i. e.*) 2, would be seen lower than 1, which is nearer: thus he has falsely represented P, O, G, *being below the line Z, X,* having given it the same appearance as that in which it is truly exhibited, p, o, g, Fig. 36, where it is *above* the line C, D, which is the same with the line Z, X, Fig. 35. P, O, G, Fig. 36. is also a true representation of the figure as it should have been given by *Bosse*.

Fig. 37. Here is added another figure of *Bosse*, being a cube resting on one of the solid angles, for which (by way of preparation) the geometrical scheme *above* is by him given, but not sufficiently explained. Some lines therefore are added to render it more intelligible; 1st, the square g, n, o, p, is made, then the diagonal n, p, drawn, which is transferred by the pricked arch p, b, to the point b, in the line n, g, and the line b, a, drawn parallel and equal to g, p, and then n, a, is drawn, and b, 7, perpendicular to, n, a, cutting it in 7, and from b, as a center, with the interval, or radius, b, 7, a circle is described, in which two regular equilateral triangles 1, 3, 5, and 2, 4, 6, are inscribed; thus b, n, o, a, represents, geometrically, the cube standing on the point n, b, n, and a, o, being profiles of two opposite faces seen anglewise; (*that is, representing diagonals of the cube,*) b, a, and n, o, of two other faces seen laterally; b, 7, and o, 8, two semidiameters (together) equal to l, m, or (1, 4;) n, a, is the axis, to which are added the double line l, n, m, and the two perpendiculars b, l, and o, m; l, n, m, represents the profile or section of the ground or plane on which the cube is supposed to rest, as on the point n; and n, b, (being equal to n, p, the diagonal of a face) is the profile of the face B, P, C, F, (represented below;) B, representing n, and l, b, (equal to 7, n,) is the perpendicular height of the point b, in the geometrical scheme represented by C, 1, 3, G, and 5, H, in the perspective; as o, m, equal to 7, a,
or

or 8, n, the perpendicular height of the most distant point, and two others represented by 4, I,—2, P, and 6, F, in the perspective; for n, a, is the greatest height, being the axis of the cube, represented in the perspective, by A, B; and these three are all the perspective heights.

The manner of performing the perspective, according to *Bosse*, has been before explained; and it is to be carefully remarked, that, in order to find these perspective perpendiculars, the measure must be first taken with the compasses, above, on the geometrical; the compasses thus open must be applied to that chequer, to see how many squares, and parts it contains, and then the same proportion must be taken along the parallel squares of the perspective, even with that point in the perspective plan, from which the perpendicular is required. For instance, to find the point c, in the perspective, take the measure l, b, with the compasses, apply them to the geometrical squares, where it appears, that this line l, b, is equal to r, s, in the geometrical chequer (*i. e.*) two squares, and a part of another; then from the point r, in the perspective measure, take two squares and such part from r, to r_o, and make r, c, equal to it, by applying the compasses, thus open, from r, perpendicularly to C, and so for every height.

Fig. 38. No. 1. Is the same cube by the method so often explained; and here it is only necessary to require that a cube be represented perpendicularly on its axis, and after the center, and distance of the picture are given, to give, also, the point B, the pole of the axis, on which it stands: C, D, is the distance, wherefore make the angle C, D, W, equal to b, n, l, (Fig. 37, No. 1.) the inclination of the nearest face of the cube (b, n,) with the ground, n, l, and draw D, O, perpendicular to D, W; then draw B, O, and from B, draw B, i, parallel to D, O, and (in order to find the proportional length of B, i,) draw B, z, parallel to C, D; then make r, t, on the ground line, equal (geometrically) to a side of the cube, and draw t, Z, cutting z, B, in y; then y, z, is the proportional length, at B, which set off from B, to, i; now draw D, i, cutting B, O, in I, then B, I, is one line determined. Fix one foot of the compasses in W, and with the other, set off the distance W, D, to D, and also the same distance on each side of W, towards

a, and b, which will be the vanishing points for the sides of the nearest (or front) face of the cube B, P, C, F, and its opposite face A, G, I, H; draw a, B, P, and b, B, F, and B, *f*, parallel to *D*, b, make B, *f*, equal to B, *i*, draw *D*, *f*, cutting B, F, in F, draw B, *p*, parallel to *D*, a, and equal to B, *i*, and draw *D*, *p*, cutting B, P, in P; draw a, F, and b, P, meeting in C, then B, P, C, F, will be one face determined; draw C, O, F, O, and P, O, and a, I, cutting P, O, in G, and b, I, cutting F, O, in H, and draw a, H, and b, G, meeting in A, which completes the whole cube.

Fig. 38. No. 2. The only difference between the operations to produce this figure, and the last, is, that here instead of finding B, I, B, P, and B, F, the diagonal B, C, is found, by drawing from W, its vanishing point, through B, and the length of it, by drawing B, *c*, parallel to *D*, W, and equal to the geometrical length of the diagonal *n*, *p*, (for this cube is supposed to stand on the ground line, and not within, as No. 1.) and drawing *D*, *c*, cutting W, B, in C.—Besides which, the length of B, I, is also found as before, so that this whole representation of the cube will be produced, by finding the length of two lines only, and these determine the lengths of all the rest, by means of the same vanishing points that served for the other. And in the same manner, many other cubes might be represented by the points already found.

N. B. The length of this diagonal B, C, No. 2, as well as of the line B, I, in both the cubes, might be found by other ways, which are sufficiently explained elsewhere; however, to give an instance, as W, *D*, is set off to *D*, the line B, *c*, might have been drawn parallel to W, *D*, and then drawing from *D*, through *c*, would find the point C; for it is shewn, in the beginning of this treatise, that the truth of these things depends on the parallelism of the original line with its line of distance, and not on their direction.

And at No. 1, if the distance O, *D*, had been turned up on the point O, till that line became parallel to C, *D*, then B, *i*, might have been also drawn parallel to C, *D*, and if a, *D*, had been turned down

on

on the point *a*, and *b*, *D*, on the point *b*, both to the line *a*, *W*, *b*, then *B*, *p*, and *B*, *f*, might also have been drawn parallel to *C*, *D*.

Fig. 39. Is also from *Bosse*; the geometrical is above, which needs no explication:—And for the perspective (according to him) the horizontal plane in the picture must be chequered, perspective, by means of the point of sight, or center of the picture *X*, and distance *Z*, the ground line *E*, *V*, being divided into six equal parts by the numerical figures, above that line, for feet, corresponding to the same number in the geometrical; then the line *o*, *X*, below, in the perspective, which is the seat of the line 3, *a*, must be divided perspective (to represent the geometrical lines above, *o*, *g*,) and marked with the same figures from *o*, to *g*, inclusive: to effect which, set it off geometrically on the ground line from *o*, to *V*, dividing *o*, *V*, by the figures below that line, and from the several divisions draw to *Z*, cutting the line *o*, *X*, in 1, 2, 3,—4, 5, 6,—7, 8, 9. Then from each of those divisions erect perpendiculars, which must be made (perspective) equal to their correspondent perpendiculars in the geometrical scheme above; for instance, the perpendicular *g*, above, being taken by the compasses, and one foot set on *E*, *V*, at *E*, the other foot reaches to the middle of the square between 4, and 5, (*i. e.*) four feet and a half; wherefore, on the parallel at *g*, in the perspective line *o*, *X*, take $4\frac{1}{2}$ feet, and at *g*, turn the compasses up, with that opening, perpendicularly over *g*, which reaches to *a*, and determines the length of the line 3, *a*, and 3, touching the ground, its place is thereby determined; so that drawing *a*, 3, finds that line, and the perpendicular at 7, is found in the same manner, (*i. e.*) by taking its measure from the geometrical above, which applied to *E*, *V*, appears to be 5 feet $\frac{1}{4}$; and then on the parallel 7, in the perspective, taking $5\frac{1}{4}$, and turning up the compasses (as before) the point *b*, is found; and thus is found the point *c*, below; then by joining *c*, *b*,—*b*, *a*,—and 3, *c*, one side of the beam *a*, *b*, *c*, 3, is found; then from *b*, and *c*, and also from 1, in the perspective line *o*, *x*, draw parallels towards *E*, *Z*, and from the parallel of the last, raise a perpendicular to *e*, and draw *e*, *f*, and raise another perpendicular from the parallel of 7, (*i. e.*) at *k*, (in the
line

Fig. 38. No. 2.

Fig. 37.
No. 1.

The true point a. is at the intersection of
D a with W. a. beyond the picture.

The true point b. is at the
intersection of D. b. with W. b.

line E, *f*, X,) equal to 7, *b*, which finds the point *g*; draw *e, g*, which completes this beam: the parallels, found on this, being continued, will serve for those of the other beam, and with correspondent perpendiculars, it may be completed.—Then for the cross bar, perpendiculars from 4, 5, and 6, in the perspective line *o, X*, respectively measured, first in the geometrical, then on the perspective parallels, will find all the points necessary, by which the whole is completed.

Fig. 40. Is the same object represented by the method herein proposed. Let the geometrical be either drawn as above, or only the form, and measures given in words, with the position, in consequence of which, draw *h, i*, (or any other known, or given line); and having found *S*, the center of the picture, and *D*, the distance, by means of the terms given, set off the same distance, upwards, from *S*, to *d*, and downwards from *S*, to *b*, then the angle *d, D, b*, will be a right angle, and the angles *S, D, d*,—*S, D, b*, each of them 45 degrees, as will also the angles *D, b, S*, and *D, d, S*, which is the angle of inclination of the original object with the ground, (as well as with the perpendicular *9, 10*, in the geometrical above) wherefore *d*, is the vanishing point for *i, k*, and all its parallels, and *b*, for *l, i*, and all its parallels. Draw *m, p*, on the same line as *h, i*, equal to it, and at the distance given, from it; then draw *i, d*,—*h, d*,—*m, d*,—and *p, d*, all to the same point *d*. And for the length of them, first draw from *D*, through *m*, to *M*, in the ground line, then draw *M, a*, (which is to be considered as an original line) parallel to *D, d*, and equal to the geometrical length of the originals, which are all equal. Now divide *M, a*, as 3, 10, (the original above) is divided, (*i. e.*) in *z*, and *q*, and draw *z, D*,—*q, D*, and *a, D*, cutting *m, d*, in *Z, Q*, and *n*, which will be the perspective points answering to *z, q*, and *10*, in the geometrical. Through *Z*, and *Q*, draw from *b*, two lines *Z, r*, and *Q, s*, and then cut these last lines from the perspective divisions of 4, *m*, found by like means, (explained a few lines lower); and thus the four points, for the cross beam, are determined, in the plane 4, *m, n*.

N. B. *o, S*, is the seat of *A, d*, on the plane of the horizon, which two lines cut each other in angles of 45 degrees perspectivevely, as their originals do geometrically.

For the squares at the bottoms, and tops, draw $b, i, —b, h, —b, m,$ and $b, p,$ also $b, k, —b, n;$ then from $g,$ draw $g, h,$ cutting $b, i,$ in $l,$ and $g, p,$ cutting $b, m,$ in $4;$ drawing also from $g,$ through the divisions of $p, m,$ are got those of $4, m;$ for $g,$ is the distance of the vanishing point $b,$ (equal to $D, b,$) and therefore is the vanishing point of the diagonals $p, 4,$ &c. on $b, g,$ the vanishing line of the plane $b, l, i, —p, 4, m,$ and their parallels. Now draw $l, d,$ and $4, d,$ &c. Lastly, the cross beam is finished, by drawing its parallels, having before found the several points by means of the vanishing points $b,$ and $d;$ and this completes the whole.

Fig. 41. At the end of this treatise of *Bosse* a figure is proposed, which he calls a cage, and which is also inserted in the Jesuit's perspective borrowed from this; and, in both, said to be by the universal method of *Monf. Desargues*. Its excellence consists in this, that by it the object may be projected as large as the picture, by lines and points all within the compass of it;—now, besides that it might be more accurately done apart, and transferred to the picture with much less than one quarter of the work, and in less than one quarter of the time, it may also be done within the same compass, in a shorter, and less complicated way, and with fewer lines, as follows.

The same circumstances, *viz.* shape, size, and particular measures, are given, as are given by *Bosse*, with its situation, height of the horizon, distance, and vanishing points; all which are expressed geometrically on the side, in a small scale from him. The same letters are also used throughout, as many at least as are necessary here, that the two schemes may be more readily compared. Having marked $G,$ the point of sight, or center of the picture, take so much of the true distance as comes conveniently into the picture; for instance one fourth, which is 6 feet (the distance given being 24) set it off from $G,$ to $Z,$ on the horizontal line.

$A, B,$ is the ground line divided into 12 feet, draw $A, G,$ and $B, G,$ and rays to $G,$ from 12, to 7, inclusive.

Now in order to find any point, as $M,$ which is 17 feet within the picture, and $1\frac{1}{2}$ from $A, G,$ towards $B, G,$ as appears by the small

geometrical scheme above, take from A, towards B, $\frac{1}{4}$ of 17, that is, $4\frac{1}{4}$ feet, and thence draw to Z, cutting A, G, in R, which will be 17 feet within the picture, (for if Z, was 24 feet from G, and 17 feet had been taken from A, towards B, a line drawn from Z, *so placed* to 17, would have cut A, G, in the same point R, the proportion being exactly the same. Then through R, draw a parallel to A, B, and, on that parallel, measure 1 foot $\frac{1}{2}$ between 7, and 12, (which is a perspective scale;) transfer that measure to R, and set it off from R, to M; thus the point M, is found.

K, is 29 feet within the picture, and $7\frac{1}{2}$ behind A, G; therefore from A, towards B, take $\frac{1}{4}$ of 29, which is $7\frac{1}{4}$, and draw from thence to Z, cutting A, G, in e, which will be 29 feet within;—through e, draw a parallel, and on that parallel measure 7 feet $\frac{1}{2}$, which measure carry to e, and set it off to K;—then for L, which is 26 feet deep, draw from $6\frac{1}{2}$ (on A, B,) being one quarter of 26, to Z, which finds a point in A, G, 26 feet within; and on the parallel drawn through that point, set off 13 feet $\frac{1}{2}$, being its distance from A, G, measured as before; that is, on this parallel take the whole line from e, to its intersection with G, B, which is 12 feet, and add $1\frac{1}{2}$ of the same measure, which will determine the point L.

In like manner for the point I, which is 38 feet within, draw from $9\frac{1}{2}$, the middle point between 9, and 10, to Z, which will cut A, G, 38 feet deep, and from this last intersection set off on the parallel in which it lies $4\frac{1}{4}$ perspective, as before for the others; join M, K,—M, L,—L, I, and I, K, which completes the lower square of the cage.

The perpendicular sides are all 17 feet high, wherefore take 8 feet $\frac{1}{2}$, (the half of 17) on the *parallel of each point*, M, K, L, and I, and doubling them over each point, respectively, the four corners, above, are determined, and by a like means the apex is found; (*i. e.*) after having drawn the diagonals of both squares, draw an indefinite perpendicular through both centers upwards; then take, on the parallel of the center of the lower square, 13 feet $\frac{1}{4}$, being the height of the apex, above the upper square, and mark it on the perpendicular drawn, to

which draw lines from the four corners, this completes the whole object.—The work is apparently less than his, for besides that he makes use of a double operation for three of the four angles, merely to find their depth, which are found here by a single one, and all the four by the same method; this double series of numerical figures, which in his method is necessary, is apt to confound, and it requires much time, and great care, to divide the lower series with exactness, which is wholly unnecessary in the method here used.

Fig. 42. In the second Volume of *Pozzo*, Plate 9, these eight pilasters placed circularly are represented by his shorter method, which has been before sufficiently explained. The lines are all left, that the quantity of work may be seen, and none are drawn, but such as are necessary, those tending to O, are drawn only on one side of B,—because the other side exactly corresponds; so that having placed one foot of the compasses on the point B, the other is to be extended to the several divisions, and to be transferred each twice, that is, on both sides of the point C, as the objects are placed at equal distances from it on either side; for instance, B, 1, is set off from C, both ways, and so of the rest.

Fig. 43. The same subject according to the new method. And here the double circle is first made perspective, as has been taught, then at the point of distance $D^{\frac{1}{2}}$, a geometrical double circle is drawn with one square, A, B, in its plane, as a plan of one pilaster, and $D^{\frac{1}{2}}$, A, $D^{\frac{1}{2}}$, B, drawn, which find a, and b, on the vanishing, or horizontal line; these would be the true vanishing points, if $D^{\frac{1}{2}}$, was the true distance, but it being only half, the distance C, a, is doubled to a^2 , and C, b, to b^2 , which become the vanishing points, (for the triangle C, $D^{\frac{1}{2}}$, a, being half of, and similar to, what the true distance would produce, c, a^2 , is the base of that triangle); wherefore drawing a^2 , S, and b^2 , S, the perspective plans of the pilasters 1, and 5, are found, and setting off the same measures from C, on the other side, and thence drawing through S, as before, the plans of 4, and 8, two more of the pilasters, are also found; but there not being room for the vanishing points of E, F, the next pilaster in the geometrical plan, (which would complete the whole) another operation becomes necessary,

Fig. 13.

cessary, *viz.* the geometrical place of that pilaster, or its opposite, must be found below, as at G, and represented, as was explained in the first plate of this treatise; the plan of No. 2, will then be found, the sides of which being continued through S, finds also the plan of 6; the remaining two are found by parallel lines from those already done; for 3 is parallel to 6, and 7 to 2; then the geometrical height is set perpendicularly from e, to f, and lines drawn from both to C, between which all the several heights are found by means of parallels drawn from the bases or plans cutting e, C; and perpendiculars from those interfections to f, C, and parallels drawn back from the interfections of f, C, complete the whole.

Fig. 44. This is another representation of the same pilaster, added merely to shew how little work is necessary, where room is not wanting for all the vanishing points; and this representation is so easy to be understood, merely by inspection, after what has been said above, that no explanation is necessary.

Indeed this alone might have been sufficient to have shewn the practice; but then it might have been objected, that the Fig. 43. was avoided, to conceal the difficulty of this method, when the space allotted is too small to receive all the vanishing points necessary; but for the future, such a distance will be taken, as may admit of all, or most of the vanishing points; both because the work will be clearer, and shorter, and also because a proper place is reserved in the fourth part, for the explanation of several expedients that may be used, in cases that shall require them.

The THIRD PART.

THE reader is supposed, by this time, to be sufficiently convinced, that the new method is preferable to any former; therefore no more comparisons will be made, but the new principles constantly recommended in this treatise will be regularly pursued.

Perspective is principally exercised in projecting points and lines, and planes composed of lines; for solid bodies, of all kinds, are to be projected either by two planes perpendicular to each other, as the ichnography, and orthography, or by that number of planes which compose such bodies respectively; in either case it is necessary, after having found the vanishing line of each plane, (the center and distance of the picture, on which it depends, being always given) to project the several lines which form such plane. When the whole number of planes are projected, the body or figure is completed by such projection, without any further operation; but when only the two planes of the ichnography, and orthography are chosen to be projected, it is necessary, afterwards, to join their corresponding points, by perpendiculars drawn from them respectively.

It is apprehended, that the following examples will be sufficient to explain, and illustrate these two manners of projecting objects, respectively.

Here it may be proper, more explicitly, to describe the nature of vanishing points, and lines, (hitherto occasionally explained) and to shew how they are generated.

A vanishing point, is that point, wherein a line, passing from the eye, parallel to an original line, cuts or intersects the picture; and a vanishing line, is that line wherein a plane, passing from the eye, parallel to an original plane, cuts or intersects the picture. Thus the point, commonly called the point of sight, or center of the picture, being determined by a line passing from the eye, at right angles, or perpendicular to the plane of the picture, is the vanishing point of all original

Fig. 42. N^o. 2.

Fig. 42. N^o. 3.

Fig. 42. N^o. 1.

Fig. 44.

original lines, making right angles with, or which are perpendicular to, the plane of the picture. And when the picture is perpendicular to the plane of the horizon, which is the most ordinary situation, the line, commonly called the horizontal line, being formed by a plane passing from the eye, at right angles, or perpendicular to the picture, is the vanishing line of the horizon, as well as of all other planes parallel to the horizon; but when the picture is inclined to the horizontal plane, in any other than a right angle, then the vanishing line of the horizon will be higher or lower than the vanishing line of a plane perpendicular to the picture, according as the picture is inclined backwards or forwards, as shall be explained hereafter.

And thus, in general, the vanishing line of any original plane, is that line in which the parallel of such original plane (passing from the eye) cuts the picture.

Fig. 45. Let it be required to represent a cube standing on a plane, making a given angle with the horizon, (suppose thirty degrees) the point of sight, or center of the picture, and the distance being given. First mark the center of the picture S , and draw S, D , parallel to the intersection of the original plane with the picture, and equal to the distance given; through S , draw S, P , perpendicular to S, D , and from D , draw D, C , making the angle S, D, C , 30 degrees; and cutting S, P , in C , draw d, C , parallel to S, D , which will be the vanishing line of the plane on which the cube stands; draw D, P , perpendicular to D, C , cutting S, P , in P , and bisect the angle C, D, P , to X , and set off the distance (D, C) of the vanishing line, d, C , from C , to d , then will the points C, P, X , and d , be all the vanishing points requisite for projecting the cubes No. 1. and 2, and as many more as may be required, with a situation, direct, on the plane, whose vanishing line is d, C ; for draw at pleasure e, f , parallel to d, C , then e, C , and f, C , and d, f , cutting e, C , in g , and g, h , parallel to e, f , which finishes the lower square, then P, e ,— P, f ,— P, g , and P, h , after which draw X — h , cutting P, f , in l , and the diagonal h, l , will determine the length of f, l ; then draw l, C , and l, u , parallel to e, f , then u, C , and the remaining parallel, by which the cube is completed.

The

The same points and operation are sufficient for No. 2, or any others in a like situation.

For No. 3, the same lines, with very little addition, (on account of the different position of it) are sufficient. This cube is in an oblique situation on the same plane; $m, 6$, is first drawn at pleasure, and continued to a , its vanishing point, then the distance of the vanishing line, *viz.* D, C , is set off from C , to D , then a, D , is drawn, and D, b , at right angles to it, and so b , becomes the vanishing point of m, q , and its parallels; the length of m, q , is taken at pleasure (as was e, f , of No. 1.) but by that all the other lines are determined. Draw q, a , and to find the length, $q, 5$, bisect the angle a, D, b , to X^2 ; draw X^2, m , cutting q, a , in 5 ; draw $b, 5$, cutting m, a , in 6 , which finishes the lower square; draw P, m ,— P, q , and $P, 6$, and to find their lengths, the distance of P, b , the vanishing line (of the plane of m, q, n .) must be found; therefore draw through S , a perpendicular to P, b , cutting it in C^2 , which will be the center of that line, and on P, b , as a diameter, describe a semicircle, cutting that perpendicular in d^3 , then P, d^3, b , will be a right angle (by 31. III. Eucl.) and consequently d^3, C^2 , the distance, of that vanishing line; or draw S, D^2 , parallel to the vanishing line P, b , and equal to S, D , (the distance of the picture) and draw from D^2 , to C^2 , (the center of P, b .) and set off D^2 , to d^3 , by placing one foot of the compasses on C^2 , and with the other foot describing the arc $D^2, -d^3$, at d^3 , bisect the right angle P, d^3, b , to X^3 , and draw X^3, q , which will find the diagonal q, n , of the square m, q, n ; draw n, a , and n, b , &c. and so complete the cube.

No. 4. Is another cube represented by means of the same vanishing points, as No. 3, without the addition of one other point or line. But because in some cases it may not be so convenient to make use of the diagonals to determine the lengths of lines, the following method is added, which is universal. Having drawn from k , to the three vanishing points a, b , and P , in order to determine the length of any line, as for instance k, i , (whose vanishing point is b .) set off b, D , the distance of that vanishing point, on its proper vanishing line a, C, b ,
from

from D , to the point o , and parallel to that vanishing line draw k, r , equal to the original of k, i , in that place : Draw o, r , cutting k, b , in i , which will be its perspective length ; make k, t , on the other side equal to k, r , and, in like manner, set off the distance of a, D , to u , on the same vanishing line ; draw u, t , cutting k, a , in w .—The same is repeated at z , (*i. e.*) the distance P, d^3 , is set off to z , on the vanishing line b, P , to determine one line in that plane, *viz.* $k, 7$, for which purpose the same geometrical length is placed from k , to 8 , parallel to b, P , and drawing $z, 8$, cuts it in 7 , the perspective length.

If it were required to find the plan of one of these cubes on the horizontal plane, this might be done by dropping perpendiculars from every point of the cube, as at No. 4, and cutting those perpendiculars by lines drawn from vanishing points found in the horizontal line S, D , by means of perpendiculars from the corresponding vanishing points of the several lines of the projected figure ; as for instance, S , is the vanishing point P , brought up to the horizontal line, wherefore draw from S , through 7 , the lower angle of the cube (supposed to touch the ground) cutting the perpendicular from k , in the point a , which is the seat of the point k , on the horizon ; from a , draw to the point perpendicularly (under b ,) in the horizontal line, which determines the plan or seat of i ; from a , draw to the point under a , which finds the seat of w ; and from these two last found points, the seats of i , and w , draw to the same vanishing points, of the horizontal plane, which completes the plan of the upper face, of the cube ; and in the same manner is the plan of the lower face found, and by joining the two extreme points on each side, the plan of the whole cube is completed.

That of No. 2. is also found in the same manner, but as one whole side of this cube touches the horizontal plane, it being placed parallel to the horizontal line, and only the point S , used, the plan is more simple. And if it were required to find the plan at any given distance below, on supposition of the object being above, and not touching the horizontal plane, the same method will answer the purpose ; thus, at No. 3, drop a perpendicular as low as required, (*e. g.*) from N , to M , and proceed as at No. 4, beginning with M .

N. B. *The finding plans of objects already projected, is by no means an useless curiosity, but in some cases absolutely necessary, and particularly, in order to the projection of their shadows.*

Suppose it required to represent an object standing on a plane inclined to the horizon, in any given angle, as (*e. g.*) in an angle of 20 degrees, and on a picture perpendicular to the horizon.

Fig. 45. No. 5. Let S, be the center of the picture; S, D, the distance, marked on the horizontal line; S, C, drawn perpendicular to S, D; and D, C, drawn so, as to make with S, D, an angle of 20, (the required inclination of the original plane, with that of the horizon,) and cutting S, C, in C. Then the angle at C, will be 70, the complement of 20, to a right angle, and equal to that which the original plane makes with the picture.

By such original plane is to be understood a plane whose intersection, with the picture, is parallel to the horizontal line, in which case its vanishing line will necessarily be parallel also: wherefore C, D², drawn through C, parallel to S, D, is that vanishing line, and C, D, its distance, which may be raised up to its vanishing line C, D².

The object, or wedge A, is an example, shewing the use of such vanishing line, the base of it is a square on the horizontal plane, projected by means of the horizontal line F, S, D. But the upper face of it inclines to the horizon in an angle of 20, and is, therefore, projected by means of the vanishing line C, D², as appears by the lines of the operation, in the diagram.

But when the original plane (though with the same inclination to the horizontal plane) is oblique to the picture, then the vanishing line of that plane will be oblique also, and will intersect the horizontal line, as E, D, the vanishing line of the upper face of the wedge B, which object is, in all respects, similar to A, its position *only* being different, and is projected on its proper vanishing line E, D, by means of points exactly corresponding to those on the vanishing line C, D², for the upper face of the wedge A.

Now, here, though the inclination of the upper face of B, to the plane of the horizon, is still the same, yet, its inclination to the plane

Fig. 15.
N. 5.

of the picture is altered by the obliquity of its position; and as the inclination of two planes is always measured on a third plane perpendicular to both (or which is the same thing) perpendicular to their common intersection; so it appears in the diagram, that the angle E, d, F , which measures the inclination of the upper face of the object B , with the horizon, is equal to C, D, S , which measures that of the upper face of A .—But that d, C^2, S , which measures the inclination of the upper face of B , *with the picture*, is larger than D, C, S , which measures the inclination of the upper face of A , *with the picture*.

And as the angle d, C^2, S , is larger than d, E, F , so the angle at d , (the complement of d, C^2, S ,) is necessarily less than that at d , (the complement of d, E, F ,) which angle at d , is the inclination of a plane, to another plane whose vanishing line would be d, S , continued, (*i. e.*) parallel to D, E , and not to the plane of the horizon.

The vanishing line E, D , for the upper face of B , is found by bringing down F, D^3 , (the distance of the vanishing line E, F ,) to d , on the horizontal line, and drawing d, E , making F, d, E , an angle of 2α , and then drawing E, D , which is the vanishing line required.

For if the triangle F, D^3, D , be raised up on the line F, S, D , so as to become perpendicular to the picture, and the triangle E, d, F , raised up, with it, on the line E, F , till d , coincide with D^3 , (in that perpendicular situation,) then it will be evident that the plane E, d, F , will be perpendicular both to the plane of the horizon, and to the plane E, d, D , (when in such situation) which plane, being parallel to the original, oblique plane, and cutting the picture in E, D , that line becomes its vanishing line.

As this part, relating to oblique planes, and especially when obliquely situated with respect to the picture, is somewhat difficult, particular attention has been employed to render it as clear, as possible, and for that purpose the two principal parts of the last diagram, are again *separately* represented, and distinctly considered, in the two following schemes, and with a greater angle of inclination to the horizon.

Fig. 45. No. 6. F, D , is the horizontal line; S , the center of the picture; S, D , the distance of the picture; E, D^2 , the vanishing line of a plane inclined

clined to the horizon in an angle of 40 degrees, and consequently to the plane of the picture in 50, the complement of 40; C, the center of that vanishing line; C, D, its distance; C, D², the same distance raised up to its proper vanishing line. This wants no farther explanation.

Fig. 45. No. 7. F, D², the horizontal line; S, the center of the picture; S, D, the distance of the picture; E, D², the vanishing line of a plane inclined to the plane of the horizon in an angle of 40 degrees, (*as is E, D², No. 6.*) but in a different direction, (*i. e.*) obliquely, with respect to the picture. For it is inclined to the picture in an angle of 55, (*and not of 50, as No. 6.*)

Now to explain the reason of this difference, it is to be considered, that, in this scheme, No. 7, the circumstances required are, to find the vanishing line of a plane inclined to the horizon, in an angle of 40, but with a certain given direction, (*i. e.*) so as to intersect the horizontal line in a given point, as D².—In order to effect which, the first step to be taken is to find the vanishing line of a plane perpendicular to the line whose vanishing point is D², (*because on such plane the inclination is to be measured, as has been before mentioned,*) therefore from S, (the center of the picture) raise a perpendicular S, D³, equal to the distance of the picture, and draw the line D², D³, and then, perpendicular to it, draw D³, F, cutting the horizontal line in F, at which point raise the perpendicular F, E, and this will be the vanishing line (sought) of a plane perpendicular to the vanishing point D², first given.

F, is the center of this vanishing line, F, D³, its distance; wherefore bring down that distance to d, on the horizontal line, and there make the angle of inclination required, by drawing d, E; and lastly, draw D², E, which is the vanishing line of the oblique plane required. And this plane inclines to that of the horizon in an angle of 40; for if the triangle F, D³, D², be raised up on the horizontal line, till it is perpendicular to the picture, and the triangle F, d, E, be raised up at the same time with it on F, E, till d, and D³, coincide; then the plane F, d, E, will be perpendicular both to the horizontal plane, and to the plane whose vanishing line is E, D², (*for in the situation described, E, D³, D², or which is the same, E, d, D², will be that plane*) and will

will truly measure their inclination; therefore those two planes are inclined in an angle of 40, as required.

But as the plane F, d, E, is not perpendicular to the picture also, it cannot measure the inclination of the oblique plane with that of the picture.

And as this is to be found by means of a plane perpendicular to both, draw S, C, perpendicular to that vanishing line, and S, D, parallel to it, and equal to the distance of the picture, and draw D, C; then imagine the triangle S, D, C, raised up perpendicularly on the line S, C, and the other planes raised up with it (as before), and, in this situation, the plane S, D, C, will be perpendicular to both the picture, and the oblique plane, (*for D, will then coincide with D³, and d, perpendicularly over S,*) and will therefore truly measure their inclination, which, thus, is found to be an angle of 55, and its complement 35, is the angle of inclination of the oblique plane, with a plane whose vanishing line would be D, S, continued, (*and not the horizontal plane*) but which would be inclined to the horizon in the angle D, S, D²; for passing thro' the center, it is the same as the real, original, or geometrical angle of inclination. From the two last diagrams, appears the difference between the relations of an oblique plane, whose vanishing line is parallel to the horizontal line, and an oblique plane, whose vanishing line intersects the horizontal line.

For at No. 6, the plane S, D, C, (when raised perpendicularly on the line C, S,) is perpendicular to all the three planes, *viz.* of the horizon, of the picture, and of the oblique plane; and therefore measures the inclination of any two of them.

But at No. 7, the plane F, d, E, when raised, so that d, be perpendicularly over S, is perpendicular to two of them *only*, *viz.* to that of the horizon, and to the oblique plane, but *not* to the picture. And also, that the plane S, D, C, (when raised perpendicularly over the line S, C,) is perpendicular to two *only* of the three before mentioned; *viz.* to the picture, and to the oblique plane; but *not* to that of the horizon.

N. B. This

N. B. This last is also perpendicular to a third plane, (*though not one of the three here required*) viz. to a plane perpendicular to the picture, whose vanishing line would be *D, S*, continued, as was before observed.

Fig. 46. Here are some circumstances explained, which were reserved for this place, both that the learner might be prepared by what has preceded, and also that he might not be embarrassed by too many lines in one diagram. *S*, is the center of the picture; *S, D*, the distance drawn in the direction of an original plane, with respect to the picture, or in which a vanishing line is required; *S, C*, drawn perpendicular to *S, D*; and *D, C*, drawn parallel to the inclination of the original plane, (*i. e.*) making with *D, S*, a certain given angle (*e. g.*) an angle of 24, and cutting *S, C*, in *C*; then the angle at *C*, will be 66, the complement of 24, and equal to the angle such original plane makes with the picture.

Now thro' *C*, draw *a, C, b*, parallel to *S, D*, which will be the vanishing line of the original plane, and on which several cubes are supposed to be placed. Let *C, S*, be continued downwards; draw *D, P*, perpendicular to *C, D*, cutting *C, S, P*, in *P*; now supposing the plane *C, D, P*, to be raised up so, as that the point *D*, (which represents always the eye of the spectator) be perpendicular over *S*, then that plane *C, D, P*, becomes perpendicular to the picture, and *P*, the vanishing point of lines, perpendicular to the planes whose vanishing line is *a, C, b*; therefore any line, as *a, P*, passing thro' *P*, and cutting *a, C, b*, will be the vanishing line of a plane perpendicular to *a, C, b*; but in order to find a third vanishing line perpendicular to both these vanishing lines already found, the distance *C, D*, of *a, C, b*, is set off on *C, P*, at *d¹*; then *a, d¹*, is drawn, and *d¹, b*, perpendicular to it; and thus *b, P*, being drawn, becomes the third vanishing line of planes perpendicular to both the others; for (as was remarked before) any line passing through *P*, meeting the vanishing line *a, b*, will be the vanishing line of a plane perpendicular to it; therefore *P, b*, is a vanishing line perpendicular to *a, b*, and it is perpendicular to *P, a*, by construction, *a, d¹, b*, being made a right angle. This vanishing line *P, b*, might

might have been found, by drawing $a, S,$ and $S, D^3,$ perpendicular to it, equal to $S, D,$ (the distance of the picture) and drawing $a, D^3,$ and $D^3, C^3,$ perpendicular to it; cutting $a, S,$ in C^3 ; then drawing $P, C^3,$ cutting $a, b,$ in b ; as is evident; and so of the rest.

$C,$ is the center of the vanishing line $a, b,$ found by drawing a line through $S,$ perpendicular to it, and the point so found in every vanishing line, is always called its center, which is to be used on such vanishing line in the same manner, and for the same purposes with respect to the plane which it represents, as the center of the horizontal line with respect to the horizontal plane; and in the same manner are found $C^2,$ the center of $a, P,$ and $C^3,$ the center of $b, P.$ —If a circle be described round $S,$ the center of the picture, with the radius $S, D,$ which is the distance of the picture, as all the radii are necessarily equal, any line from $S,$ to the circumference will be equal to, or will be properly, the distance of the picture; therefore drawing $S, D^2,$ at right angles, on the perpendicular $b, C^2,$ of the vanishing line $a, P,$ and drawing $C^2, D^2,$ it will be the distance of that vanishing line.

In the same manner drawing $S, D^3,$ at right angles, on the perpendicular $a, C^3,$ of the vanishing line $b, P,$ and drawing $C^3, D^3,$ it will be the distance of that vanishing line; $S, D,$ — $S, D^2,$ — $S, D^3,$ will all be severally parallel to their respective vanishing lines $a, b,$ — $a, P,$ —and $b, p.$ Now if $D, S,$ be raised up perpendicularly over $C, P,$ — $D^2, S,$ over $b, C^2,$ —and $D^3, S,$ over $a, C^3,$ these three points $D, D^2,$ and $D^3,$ will coincide over $S.$ —Again, if $C, D,$ (which is the distance of $a, b,$) be transferred to $d^1,$ on $C, P,$ the perpendicular of the said vanishing line $a, b,$ and $C^2, D^2,$ the distance of $a, P,$ to $d^2,$ on its perpendicular $b, C^2,$ and also $C^3, D^3,$ the distance of $b, P,$ to $d^3,$ on its perpendicular $a, C^3,$ the three points $d^1, d^2, d^3,$ being raised on their respective vanishing lines $a, b,$ — $a, P,$ —and $b, P,$ so far as that each be perpendicular over S ; these three points will all coincide, not only with each other, but also with the three first named $D, D^2, D^3.$

The learner is advised to make all these points, and lines, as familiar to himself as possible, by drawing vanishing lines in several directions, and

and especially three, to represent planes at right angles to each other, as in this scheme, for the projection of cubes, and cubical forms, in all positions; because nothing is more necessary in the practice of perspective: and if he has understood all the preceding part, it is apprehended this will not be difficult to him. In order to assist the imagination a little, let him consider the two cubes, A, and B, one of which, A, is seen direct, the blank parts to be supposed on the other side of the picture, and the lines $n, l, —l, m,$ and $m, n,$ to intersect the picture; these three lines may be conceived to be the vanishing lines of the three planes which form the solid angle of a cube, and $m, n, l,$ the vanishing points of its sides, or legs. The same thing is represented in B, with this only difference, that it is oblique, as the large scheme, just explained; for which reason, two of the legs cut the picture on this side of the angles of the cube, and the lines $a, b, —b, p,$ and $p, a,$ represent those three vanishing lines, in the large scheme, to which they are respectively parallel, and are, in both, the vanishing lines of the solid angle of the cube.

On one side is a cube E, projected as in the former, but removed out of its place of projection, that the lines might not be confounded with those of the scheme; the reader is to refer it to $g,$ within, which point (corresponding with $g,$ on the figure) the whole is supposed to be performed.

Here is a circumstance determined which before was not supposed to be required, *viz.* that it should touch the picture in the point $g,$ the body of the figure being behind the picture; to effect which, from the point D, on the line C, D, raise a perpendicular D, G, equal to one side, or leg of the cube: draw G, F, parallel to C, P, and consequently to the picture. In projecting the cube E, after having drawn $g, b,$ and $g, a,$ (*i. e.*) suppose from $g,$ in the original scheme, draw $g, f,$ parallel, and equal, to G, F, (which was made parallel to C, P,) then draw $f, C,$ tending to C, (*i. e.*) to the same vanishing point, as F, C, and representing $a,$ parallel to it; draw also $g, P,$ cutting $f, C,$ in $h,$ then the line $g, h,$ will represent G, D, and be (perspectively) equal to it, and $g,$ will touch the picture. The rest is performed as has been shewn

shewn before. All this operation is supposed within the scheme or diagram (as is said above) beginning at *g*, and then transposed to *E*, only to avoid confusion of lines in the great scheme. The other cube *K*, is supposed to intersect the picture in the lines 5, 6,—6, 7, and 7, 8, the rest being supposed behind; to represent which, another perpendicular *H, M*, is drawn on *C, D, F*, so much before the line *G, F*, as the cube is supposed to be before the picture, the rest behind; and the same method is used as for the other *E*, only the triangle *D, G, F*, is here represented by *d, g, f*, within the cube; and, in order to make it advance before the picture, in the proportion required, a line *g, t*, equal to *G, H*, is set off from *g*, parallel to the vanishing line *a, b*; and the distance *C, D*, set off from *C*, to *q*: then *q, t*, is drawn, cutting *c, g*, in *r*; and *r, P*, cutting *C, d, f*, in *5*, determines one line of the advanced part of this cube, from which the rest is finished; and when completed, the lines forming the triangular intersection, are respectively parallel to the three several vanishing lines; the uppermost passes through *g*, determining the other two. This also is performed within the scheme, the point *r*, there, answering to that on the cube, and the whole being transposed to *K*.

It appears, by these projections, that if the measures, and forms of objects, are known, they may be represented without geometrical plans, or elevations, which saves much time and trouble. And if it be required to assign the geometrical size, and situation of any figure already projected; as, for instance, the cube *E*; first draw through *f*, a line *u, w*, parallel to the vanishing line *a, b*, which line is therefore the intersection of the original plane with the picture (or what is called the ground line;) for it was before mentioned, that *g, f*, touches the picture; continue the lines *i, h*, and *l, h*, till they cut *u, w*, in *n*, and *o*; continue also *m, l*, and *m, i*, to *u*, and *w*: then having measured the angle *d^r, a, b*, in the large scheme, make *u, o, L*, equal to it, for *a*, is the vanishing point of *h, l*; draw *w, I*, parallel to *o, L*: in like manner measure the angle *d^r, b, a*, and make *w, n, I*, equal to it; draw *u, L*, parallel to *n, I*, which will complete the figure, or plan, *L, I*, in its geometrical situation, and

proportion.—Or, to avoid the trouble of measuring, and transferring the several angles, continue d^1 , C, upwards, till c , D^+ , is equal to C, d^1 , (which was made equal to C, D,) and make o , L, and w , I, parallel to D^+ , a ; and u , L,— n , I, parallel to D^+ , b , which will answer the same purpose.

The like operation is repeated for the cube K, on the other side, transfosed from r , (within the scheme;) to which r , on the cube, corresponds, only this cube advancing, in part, before the picture, (as appears by the ground-line v , w ,) is larger on that account; and, for the same reason, the original geometrical square, or plan, is necessarily cut by the ground-line; in consequence of which the points n , o , are, in the intersection of the original square, with the representation. The rest needs no explanation, as the two figures are intirely similar.—If this large scheme appears, at first sight, overcharged with lines, the reader, who has understood the preceding rules, will readily perceive that very few of them (only) are necessary to the projection of the objects represented; and that the others are added, partly to exhibit different manners of projecting the same objects, but principally to shew the correspondence, and relation that several systems of lines have with each other, which, thus, are more evident than if drawn in separate diagrams, and more effectually illustrate the nature and use of vanishing lines.

N. B. The whole profile of this situation of the cube K, is geometrically erected on the line C, D, M, which is taken from d^1 , where the original plan is described, in the position seen by the spectator, and represented in the perspective, where C, 5 , answers to C, d^1 , in the geometrical plan, and $\frac{1}{2}$ 5 , to $\frac{1}{2}$ d^1 , &c. The lines crossing from the angles (in the geometrical plan) are parallel to the vanishing line a , b , and consequently to the intersection; and N, M, answers to N, M, the section or profile of the plan.

Fig. 47. In this scheme the vanishing line a , b , is still more oblique, and crosses that of the horizon, in order to shew that even in such situation, the manner of finding a plan on the horizontal plane is the

Fig. 45.

Fig. 46.

same as before exhibited, notwithstanding a seeming difficulty arising from the vanishing point *a*, being below the horizon.—The cube *A*, being projected, as has been before taught, in order to find its plan perpendicularly on the plane of the horizon, first transfer the three vanishing points *a*, *b*, and *P*, perpendicularly to the horizontal line, viz. *b*, downwards; *a*, and *P*, upwards, to *b*, *a*, and *p*; then draw, from the point *I*, which touches the ground, to *a*, and to *b*; drop a perpendicular from *II*, to *2*, and raise one from *III*, to *3*; then draw from *2*, to *a*, and from *3*, to *b*, which will complete the plan of the lower square or face *I*, *II*, *III*, *IV*; for the intersection of *2*, *a*, and *3*, *b*, will mark the point *4*, perpendicularly, under *IV*; now draw from *p*, through *I*, and drop a perpendicular from *V*, intersecting *p*, *I*, in *5*, and draw *5*, *a*,—*5*, *b*; drop a perpendicular from *VI*, to *5*, *a*, cutting it in *6*; and from *VIII*, to *5*, *b*, cutting it in *8*; draw from *8*, to *a*, and from *6*, to *b*, which will complete the plan of the upper face *V*, *VI*, *VII*, *VIII*; for the point *7*, will be found in the intersection of *8*, *a*, and *6*, *b*, perpendicularly under *VII*; after which, joining *I*, *5*, which is the plan or seat of the line *I*, *V*, and *7*, *4*, the seat of *VII*, *IV*, the ichnography of the whole figure is determined on the plane of the horizon, and it will be found, on inspection, that every line, and, consequently, every face, is planned, which is easily examined by the corresponding figures.

The figure *B*, is not a cube, but a right angled solid, or parallelepiped, four of whose faces are parallelograms, as in the geometrical *D*, *i*, *g*, *h*, on the line *C*, *D*, and whose upper and lower faces are squares, as appears by the diagonal drawn from *x'*, which is a bisection of the right angle *a*, *D*, *b*, and whose sides are equal to *h*, *i*; but the depth of the whole figure is only equal to *h*, *g*; and, in order to determine that depth, either the angle *h*, *D*, *g*, may be transferred to the vanishing line of one of the faces, as here to *a*, *P*, by making *a*, *d'*, *f*, equal to it, (*d'*, *c'*, being the distance of that vanishing line,) and drawing *f*, *l*, cutting *m*, *P*, in *n*; and then *n*, *l*, will be a diagonal, representing *D*, *h*, by means of which the figure may be completed.—Or otherwise, thus: drawing, *l*, *o*,

parallel to a, P , and equal to g, h ; and transferring the distance P, d' , to e , on the vanishing line P, a ; and drawing e, o , cutting l, p , in q , the length l, q , is determined, by which the rest may be finished.

There is another kind of plan which may be projected on the plane of the horizon, by lines perpendicular to the oblique plane, on which the object is supposed to stand; for this the reader is referred back to Fig. 46, at the cube E , where the vanishing points used are S , and t , on the horizontal line in the large scheme, in which the vanishing points a , and b , are transferred to that line, by a, P , and b, P , representing perpendiculars to the vanishing line a, b , of the original oblique plane. Now at the cube E , draw h, s , and h, t , then i, P , and l, P , intersecting them, in 5 , and 6 ; draw $5, t$, and $6, s$, which completes this plan; for as it is formed by the continuation of the sides of the figure which are perpendicular to the plane on which it stands, the plan of one face is (necessarily) that of the whole cube; the point h , being supposed to touch the horizontal plane.

As cubes, and cubical forms, are apprehended to be more useful than any others, as approaching nearer to those of buildings, and most common objects, they have therefore been considered in many various situations: the plans projected after the figures themselves, if not always necessary, are sometimes so, as was before observed, and were exhibited on account of difficulties that had been supposed relating to such projections. Thus having sufficiently treated of the cube, and there being no more than five regular bodies, or solids, it might be deemed an omission wholly to neglect the other four; wherefore here are given representations of them all, by the vanishing lines of their faces, and, of several, by means of the ichnography, and orthography, also, to shew the different ways of proceeding. On the side of Fig. 48. is a geometrical description of the several angles, as well of the section as faces, of a tetraedron, which must be understood before a perspective representation can be made.— G, H, I , is an equilateral triangle (whose angles are each 60 degrees) the base of a tetraedron.— I, N, K , is the section supposed to be raised up, perpendicularly, on the line I, K ;
in

Fig. 47.

in which situation the angle I, K, N, represents the inclination of two of the planes or faces; the other two, *viz.* I, N, K, and K, I, N, represent the angle made by one side with a plane or face; I, K, is the diameter; and O, N, the axis.

N. B. By referring to this, occasionally, the reasons of the following operations will be better understood.

Fig. 48. No. 1. The tetraedron A, B, F, E, is thus projected. First draw, at pleasure, the vanishing line *a, S, c*; from S, raise a perpendicular to D, the distance given; let the side B, A, be also given, which continue to its vanishing point *b*; draw D, *b*: Then make an angle of 60 degrees on each side D, *b*, to *a*, and *c*; draw B, *c*, and *a, A*, cutting B, *c*, in F; then the base, or one face, is finished on the plane of *a, S, c*.—Now find the vanishing line, *c, h, f*, of planes, inclining to the face A, B, F, in the angle of inclination of two of the faces; that is, in the angle I, K, N; on the side B, F; that is, on its vanishing point *c*; and in it find the vanishing points *e*, and *f*, (*c*, being already found) and then drawing *e, B*, and *f, F*, the point E, is determined by their intersection; wherefore joining E, A, the tetraedron is completed.

N. B. The angle of inclination of two planes is always measured, as hath been already said, on a plane perpendicular to both of them; that is, perpendicular to their common intersection. Now D, *c*, (if turned forwards with D, S, till D, S, is perpendicular to the picture) is that intersection; therefore draw D, *g*, at right angles to D, *c*, and from *g*, erect a perpendicular (to *a, S, c*.) as *g, h*, which will be the vanishing line of planes, perpendicular to D, *c*, the common intersection; and D, *g*, being the distance of that perpendicular vanishing line, set it off on either side of *g*, as at *d*; there make the angle of inclination, *g, d, b*; then draw *c, h*, which will be the vanishing line of the face B, F, E: Find the distance of this vanishing line (*i. e.*) draw from S, a perpendicular to *c, h*, cutting it in C, which is its center; set off S, D, to *d*, parallel to *c, h*, then *d, C*, will be the
distance

distance of that vanishing line, which transfer to C, D , perpendicular on it; draw c, D , and make c, D, e , and e, D, f , both 60 degrees. If any difficulty remain concerning the distance of the vanishing line c, h, f , let it be conceived that d , and D , are both brought forward, so as to be perpendicular to the picture over S , then they will coincide, and be the place of the eye; whence it will be evident, that d, C , must be the distance of the vanishing line c, h, f .

The vanishing line of a plane, perpendicular to another plane, is determined, by finding *only* the vanishing point of lines perpendicular to such given vanishing line, because any line, perpendicular to a plane, makes an angle of 90 degrees with that plane every way: whereas a line, cutting a plane in any other angle, (for instance 30) makes that angle but one way on that plane, wherefore it is necessary, in order to find a plane at 30 degrees, to take another method: and, for the same reason, a plane passing through a line perpendicular to another plane, will continue always perpendicular, though turned round such line every way. But if a plane were to be turned round a line making an angle of 30, &c. the angle would vary continually, so as to make every other angle between 30, and its complement 150, (*i. e.* to 180, or two right angles;) for this reason, it becomes necessary, in order to find the vanishing line of a plane intersecting another plane at 30, (or any other angle except 90,) to find, first, the vanishing line of a plane, perpendicular to the intersection of the two planes, whose inclination is sought, on which to measure that angle of inclination, otherwise it cannot be truly found.

Fig. 48. No. 2. *N. B.* In this scheme, B, C, G , is the vanishing line of the plane perpendicular to E , which is the vanishing point of the intersection of the planes B, E , and E, C , inclined to each other in 30 degrees; B, A, C , the geometrical angle of 30 degrees; G, A , (equal to G, D ,) being the distance of the vanishing line B, C, G ; so that if D, S , be raised up perpendicularly over S , and the

the arc A, D, together with it; and also if the triangle B, A, C, be raised on the line B, C; the point A, will move along the arc A, D, till A, coincide with D, which is the true situation; then will B, A, C, be a plane perpendicular to D, E, the intersection of the two planes B, E, and C, E.

No. 7. of Fig. 45.—S, is the center of the picture; S, D, the distance; the line A, S, D, is a vanishing line of planes perpendicular to the picture; and E, D², another vanishing line, parallel to A, S, D; but of planes inclining to the planes, whose vanishing line is A, S, D, in the angle S, D, C.—F, D², is the horizontal line.

It is required to find the angle of inclination, of the plane of the horizon, with the planes whose vanishing line is E, D², and the difference of the angles of inclination, between that of A, S, D, to E, D², and that of F, D², to the same E, D².

Set off the distance of the picture S, D, to D³, perpendicular to the horizontal line; draw D², D³, and D³, F, perpendicular to it; at F, raise the perpendicular F, E, cutting D², E, in E; then E, F, will be the vanishing line of planes, perpendicular to both the planes of E, D², and F, D²; from F, set off F, D³, (the distance of the vanishing line E, F,) to d, on the horizontal line. Now draw d, E, and E, d, F, will be *geometrically* the angle of inclination sought; (*i. e.*) of the plane of the horizon, with the planes whose vanishing line is D², E, *which was the first thing required.*

And this angle E, d, F, is larger than S, D, C, by 5 degrees, *which was the second thing required.*

N. B. The angle of inclination of the planes of A, S, D, and F, D², is A, S, F, or D, S, d, the real geometrical angle, made by their intersection, on the picture; because they both pass through S, and are therefore both perpendicular to the picture.

The representation, Fig. 48, No. 1, was formed entirely by vanishing lines; but the principles are so general, that many other methods may

may be used, some of which are still shorter in particular cases; as an instance, here is added one other projection of the same object, with one vanishing line only.

Fig. 48. No. 3. After having found the face *A, B, F*, No. 2, as before at No. 1, draw *B, a*, and *c, A*, meeting in 1, and *F, b*, and *A, c*, meeting in 2; draw 1, *F*, and *B, 2, 3*, whose intersection *o*, will be the center of the face *A, B, F*; erect a perpendicular at *o*, and, at 3, raise the perpendicular *3, 4*; set off *3, D*, (the distance of the vanishing point 3,) of either side, on the vanishing line *a, S, c*, as at *e*; draw *e, 4*, making the angle *3, e, 4*, equal to *O, I, N*, and cutting the perpendicular *3, 4*, in *4*, which will be the vanishing point of the side *B, 5*; and the line *4, B*, will cut the perpendicular *o, 5*, in the apex; from whence draw to *A*, and to *F*, by which the whole is completed.

N. B. *e, 4, f*, represents the section *I, N, K*, in the geometrical.

Fig. 49. For the octaedron, make an equilateral triangle *R, F, G*; draw its diameter *F, L*; on *R, G*, describe a square; draw the diagonal *R, H*, and from *H*, and *R*, with the radius *F, L*, describe two arches intersecting each other in *I*; then the angle *R, I, H*, will be the angle made by two planes, or faces of the octaedron on the inside; and the angle *K, I, H*, will be the angle on the outside, or (properly) the angle of inclination, and to be used in projecting this figure; for *R, H*, is the axis of the solid, and *R, I, —H, I*, the diameters of two faces meeting in *I*.

Fig. 49. No. 1. To project the octaedron, perspective, *a, S, c*, is the given vanishing line of the plane on which it rests; *A, B*, a given side of the figure, continued to its vanishing point *a*; make *S, D*, equal to the distance given; draw the lines *a, D*, and *D, b*, making with *a, D*, an angle of 60 degrees; and *D, c*, making the same angle with *D, b*; then draw *A, c*, and *B, b*, cutting *A, c*, in *E*, which finishes the face on which the solid rests; then find the vanishing line of one other face, (which will be all that is necessary;) and, in order to it, find *k*, the vanishing point of lines perpendicular

to the lines whose vanishing point is *a*; (*i. e.*) draw *D, k*, perpendicular to *a, D*, cutting *a, S, c*, in *k*; draw *k, l*, perpendicular to *a, S, c*; find its distance *k, m*, by setting off *K, D*, to *m*; from *m*, draw a line downwards to *l*, making an angle *k, m, l*, equal to *K, I, H*, (in the geometrical) with the line *a, S, c*; which line *l, m*, if continued upwards, would make an angle with the same line *a, S, c*, equal to the inner angle of the inclination of two faces; then draw *l, a*, which is the vanishing line sought; find its distance *C, D*, (*i. e.*) draw *S, C, D*, perpendicular to *l, a*; set off the distance *S, D*, to *d*, parallel to *l, a*; then set off the distance *d, C*, from *C*, to *D*:—*l, a*, thus found, is the vanishing line of the face *A, B, h*, and its opposite *g, E, i*. Now find the vanishing points, as directed above in the last figure; then draw *e, A*, and *B, f*, cutting it in *h*; then *h, b*, and *h, c*, and *e, E*, cutting *h, c*, in *i*; draw *i, a*, cutting *h, b*, in *g*; draw *g, A*,—*g, E*, and *i, B*, which will complete the whole.

Fig. 49. No. 2. Is a representation of the same figure standing on one of its points, or solid angles, with very few lines. For this projection, first draw any one given side *1, 3*, to its vanishing point *a*; find *b*, the vanishing point of lines perpendicular to those, whose vanishing point is *a*, and draw *1, b*; then draw *3, b*; bisect the angle *a, D, b*, to *o*; draw *o, 1*, cutting *3, b*, in *4*; draw *a, 4*, cutting *1, b*, in *2*, which finishes the square *1, 2, 3, 4*; at *o*, drop a perpendicular; set off the distance *o, D*, to *e*; thence draw *e, p*, making with *o, e*, an angle of 45° ; and, having found the center of the square *1, 2, 3, 4*, and drawn a perpendicular through it, draw *p, 1*, cutting that perpendicular below in *6*, and *p, 4*, cutting it above in *5*; from these two extreme points of the axis, draw to *1, 2, 3, 4*, which will complete the whole. For *1, 5, 4, 6*, represents a square (as well as *1, 2, 3, 4*;) and *o, e, p*, being half a square, the angles are rightly found.

Though the octaedron may be projected in this position with so few lines, yet as projections, by means of the ichnography and orthography, are proper in many cases, the manner of constructing and using them is here explained in the same example.

Suppose then, No. 3, the side 1, 3, only given; draw from its vanishing point *a*, any line, where there is convenient space, as *a*, 7, 8; and from *b*, the vanishing point of lines perpendicular to those whose vanishing point is *a*, draw through 3, and 1, of the line given, cutting the line *a*, 7, 8, in 7, and 8; then, through *a*, draw *f*, *g*, perpendicular to *a*, *S*, *b*; set off the distance *a*, *D*, to *e*, and draw *e*, *f*, upwards, making (with *e*, *a*,) half the angle *R*, *I*, *H*, (in the geometrical) and *e*, *g*, making the same with *e*, *a*, downwards, so that the angle *f*, *e*, *g*, be equal to the whole inner angle *R*, *I*, *H*. Now draw *f*, 8, and *g*, 7, meeting in 9; and *f*, 7, and *g*, *S*, meeting in 10; which will form the perspective of the profile, or orthography. The plan or ichnography is so easy to be understood by inspection, being only the representation of a square, that it needs no description in words.

Now perpendiculars, from the corresponding points of ichnography and orthography, will meet in the several points which form the figure; and, by joining those points, the figure is completed; (*e. g.*) drawing from the point 8, to *b*, and raising perpendiculars from 1, and 2, of the plan, meeting 1, *b*, in 1, and 2, the points 1, and 2, in the figure itself, are found; and so of 3, 4; and by raising a perpendicular from the center of the plan, and cutting it by lines (tending to *b*,) from 9, and 10, of the profile, the points 5, and 6, in the figure, will be found also, by which it is completed.

N. B. From ichnography, the perpendiculars are geometrically such; but from orthography, perspectivevely such.

This manner of projecting the orthography, is one of the great advantages of the new principles; for, according to the old, the geometrical orthography of this figure would not have been so simple; nor, indeed, would it have been any regular figure; and in architecture (where many members are to be represented) the orthographic projections for oblique situations are so confused, as to be scarce intelligible, and give no idea of the thing intended to be represented; for proof of which the reader is referred to *Pozzo's* second Volume. — The geometrical orthography is drawn above, by which it is evident that

Fig. 49. N^o 1.

Fig. 49. N^o 2.

Fig. 49.

the profile, here made use of, is the same kind of figure, having the same lines and angles perspectivevely.

And, on these principles, the orthography may, in all possible situations, be such plain, simple, and regular draughts, as an architect would make, for an elevation, with no other change than what the perspective necessarily produces, which never exhibits the figure of any object, otherwise than as seen in nature, supposing always the same situation of object, and spectator, as required in the picture.

To shew what expedients this general method affords, and how extensive the principles are, there is added another orthography of this figure, which represents a perfect square, with the two diagonals. In some cases this orthography, and in some the other, may be most convenient, according to the distances of the vanishing points. To project the figure by this orthography, let a diagonal 4, 1, (No. 4.) be given, whose vanishing point is o. Draw any where from o, at a convenient distance, for the orthography, another line o, 4, 1; find h, the vanishing point of lines perpendicular to those, whose vanishing point is o; draw h, 4, 4, and h, 1, 1, this determines the diagonal of the orthography; then find the vanishing point of lines, making 45 degrees with this diagonal; (*i. e.*) find the center c, of p, q, the vanishing line of the orthography, and its distance c, D²; draw D², o, and then make an angle of 45 above, and below the line o, D², to q, and r; for o, is the vanishing point of the diagonal, and o, D², the distance of that vanishing point; and from these two points q, and r, finish the orthography (as was done from f, and g, in the last figure); then draw from a, to 1, and from b, through 4, of the first given diagonal, which will determine the side 3, 1, in its place; then draw from 3, and from 1, to p, and another line, a, 3, 1, below for the ichnography, which complete, by drawing 3, b, and 1, b, and h, 3, cutting 1, b, in 2, and a, 2, cutting 3, b, in 4. Now through this ichnography, drawing from p, perspective perpendiculars, these will determine all the points, as the geometrical perpendiculars did in the former figure. Lastly, lines from h, to the orthography, and from p, through the ichnography, will cut each

other, respectively, in the corresponding points, to complete the figure.

This is again represented, under all the same circumstances, with a little difference in the position, only, at No. 5; in which $h, o, b,$ is the vanishing line of the plane 1, 2, 3, 4,— $o, p,$ of the plane 1, 5, 4, 6, and $p, h,$ of the plane 3, 2, 6, 5, which are perpendicular to each other; as are the planes that form the solid angle of a cube.

These are on an oblique plane (the center of the picture being $S,$) which is the reason that the perpendiculars to the square 1, 2, 3, 4, tend to p ; whereas in that, at No. 3, those perpendiculars were parallel to each other, the figure there being on the horizontal plane; but if in that the octaedron had been seen in front, so that the lines 1, 2, and 3, 4, had been parallel to the horizontal line $a, b,$ the perpendiculars from the orthography would also have been all parallel to that line, and to each other.—The orthography of No. 3, is a section through the axis, parallel to one side 2, 1, or 4, 3; that of the last, No. 4, through the axis, and diagonal; so that here both plan and profile are squares.

N. B. Though No. 4. might have been projected, in its situation, without either orthography, or ichnography (by means of the several vanishing points) yet as, in more complicated objects, this method is very expedient, it was thought proper to shew it, first, in so simple a figure, that it might be the more easily comprehended.

Fig. 50. For the representation of a dodecaedron, by vanishing lines only.

Having the center of the picture $S,$ and distance $S, D,$ given, draw at pleasure the vanishing line of the plane of one face; and having found the center, and distance of that vanishing line, erect the distance perpendicularly to that line from that center, and there find the several vanishing points of the face proposed: this is the general method.—

Here the face $a, b, c, d, e,$ is chosen, which being supposed to lie on the horizontal plane, the vanishing line passes through $S,$ and the distance of the picture $S, D,$ is (in this case) the distance of the vanishing line; draw at pleasure $b, c,$ for one side of the face proposed, which if it be not parallel to the vanishing line, continue till it cuts that line, and from

such

Fig. 19 N° 4.

Fig. 19 N° 3.

Fig. 19 N° 5.

such interfection draw to D, and thence find the vanishing points; but as b, c , here, is parallel to the vanishing line, draw through D, another parallel, and make the several angles necessary to produce the vanishing points; (*i. e.*) describe a pentagon at D, in the position required, and divide it into triangles; continue DE, DC, DB, and DA, to the vanishing line, cutting it in 1, 2, 3, and 4, which are all the vanishing points necessary: then draw 2, b , for D, C, 2, is parallel to B, A; and draw 3, c , for D, B, 3, is parallel to E, C: then draw 1, c , cutting 2, b , in a , for D, E, 1, is parallel to C, A; and draw 4, b , cutting 3, c , in e , for DA, 4, is parallel to BE: lastly, draw 1, e , and 4, a , meeting in d , which finishes the face b, c, e, d, a .

For the next face, find the vanishing line of planes inclined to that of the face already described in the same angle as the faces of a dodecaedron are to each other, (*i. e.*) 63 deg. 30 min. externally (the angle within being 116 deg. 30 min. the complement of 63 deg. 30 min. to two right angles*. Now draw D, x , perpendicular to 4, D; from x , drop a perpendicular (to the vanishing line 4, S, 1, before found); set off the distance x, D , to d ; draw d, p , making with x, d , an angle of 63 deg. 30 min. and cutting x, P , in P, which line will consequently form an angle of 116 deg. 30 min. with the horizontal line, if continued upwards; then draw 4, P, which is the vanishing line sought; wherefore find its center C^3 , by drawing through S, perpendicular to 4, P; find its distance C^3, D^3 , (by taking the distance S, D, in the compasses); then setting one foot in C^3 , and the other at Y, in the same line, and from Y, to S_3 will be the distance, which transfer to C^3, D^3); draw 4, D^3 , and find the several vanishing points on this vanishing line, as on 4, S, 1, by making the same angles at D^3 , as at D, (*i. e.*) of 36

Fig. 50. No. 2. * The angle of inclination of two faces of the dodecaedron is found, by making a regular pentagon, and drawing any diagonal, as a, a ; then bisecting that diagonal in A, and raising a perpendicular A, B, to the opposite side, bisecting that side in B; and then with the distance A, B, as radius, describing the arcs a, b , and a, b , meeting in b , and producing a, b , to E, the external angle E, b, a , is the angle of inclination sought.

For if on the real solid any two parallel diagonals are drawn on two adjoining faces, and these diagonals are bisected, and perpendiculars drawn from each point of bisection to the side of contact, these perpendiculars will form the inner angle of 116 deg. 30 min. (very nearly): and the external angle of 63 deg. 30 min. is the angle of inclination,

degrees

degrees each, and proceed as before, for the first face; that is, taking a, d , here, for the given side, because 4, is its vanishing point, in the plane of 4, C³, P, as well as in that of 4, S, 1, the point 4, being the intersection of the vanishing lines of those two planes; draw 6, d , and 7, a ; then 5, a , cutting 6, d , in f , and 4, f , cutting 7, a , in g ; but 8, being too far distant to come within the picture, (instead of drawing 8, f , and 5, g , meeting in b , as in the first face) draw 5, g , and 6, a , cutting it in b : lastly, join b, f , which finishes this face.

Now draw a line through 2, 7, which will be the vanishing line of the face a, b, g, i, s , for 2, is the vanishing point of a, b , and 7, of g, a , both of these being sides of this face, (and two points in any right line being given, the line is thereby given); and having found the center C, and distance D^2 , of that vanishing line, with its vanishing points 9, and 10, by the same operation as the last, draw $g, 10$, and 7, b , cutting it in i ; draw $i, 9$, and $g, 2$, cutting it in s ; lastly, join s, b , which finishes this face.

If it had been necessary to have found this vanishing line (for want of a second point) the same method must have been used as for the other, excepting that the perpendicular must have been drawn upwards, and the angle taken on the upper side of the vanishing line, 4, S, 1, and from thence a line must have been drawn cutting the said perpendicular, because this vanishing line (by the situation of its original plane) must necessarily make its acute angle, or angle of inclination, above the horizontal line.

Now draw 10, 3, 5, which will be the vanishing line of the face g, b, i, k, l , for 5, is the vanishing point of g, b , and 10, of g, i , and find the other vanishing point 11, of that vanishing line (for 3, through which it passes, was before found); draw 11, i ; then draw 11, g , and 5, 1, cutting it in l , and $l, 3$, cutting 11, i , in K; lastly, join l, b , which finishes this face.

Thus having got two lines, i, k , and i, s , (of the next face i, k, m, t, s ;) whose vanishing points are 11, and 9, draw through those two points the vanishing line of this face, which will also pass through 1, and 6, the remaining vanishing points; draw $k, 1$; then draw $k, 9$, and $i, 1$, meeting in t ; draw 6, t , cutting $k, 1$, in m ; lastly, join s, t , which finishes this face. The

The uppermost face k, l, m, n, o , being parallel to a, b, c, d, e , has, of consequence, the same vanishing line, of which face the lines k, l , and k, m , being already drawn, draw $4, m$, and $l, 1$, cutting it in n , and draw $2, n$; lastly, draw l, o , parallel to b, c , which finishes this face.

The remaining four faces are opposite, and parallel to four, on the other side, and are therefore drawn by means of their respective vanishing lines; the face d, e, f, r, q , is opposite and parallel to i, k, m, t, s ; the face c, e, q, u, w , is opposite and parallel to g, b, i, k, l ; the face r, q, w, n, o , is opposite and parallel to a, b, s, i, g ; and the face t, m, n, w, u , is opposite and parallel to a, d, f, b, g : the same vanishing points, and the same manner of proceeding, determines all the points, and lines of these four, as of their opposites, though in contrary positions, and these compleat the dodecaedron.

There is one other dodecaedron on the side, which is projected by the same vanishing points.

Fig. 51. No. 1. In order to represent an icosaedron, the fifth and last of the regular solids, which is composed of 20 equilateral triangles, let one side $3, 4$, be given, with its vanishing line a, b, c , and distance S, D . Continue the given side to its vanishing point a ; draw a, D , and find the vanishing points b and c , by making a, D, b , and b, D, c , angles of 60 degrees; draw $3, b$, and $4, c$, cutting $3, b$, in 2 , which determines one face $4, 3, 2$; then through a , find the vanishing line of planes, inclining to that of a, b, c , in the same angle as the faces of an icosaedron to each other (viz. 42 degrees) being the acute angle without, (the complement of 138, the obtuse angle within *) by drawing D, q , perpendicular to a, D , and q, p , to a, b, c , which will be the vanish-

Fig. 51. No. 2. * The angle of inclination of two faces of the icosaedron is found, by making a regular pentagon, and on one side describing an equilateral triangle, and having drawn a diagonal of the pentagon, a, a , and the diameter of the triangle, as A, B ; then taking A, B , for radius, and describing the arcs a, b , and a, b , meeting in b , and producing a, b , to E , the angle E, b, a , is the angle of inclination sought.

For, on the real solid, five equilateral triangles form a pyramid, whose base is a pentagon; therefore a diagonal of that pentagon will be the base of a triangle, whose legs (being the diameters of two of these equilateral triangles) will form the internal angle of 138 deg. (nearly): and the external angle of 42 deg. is the angle of inclination.

ing

ing line of planes perpendicular to the lines, whose vanishing point is a ; then setting off the distance of that vanishing line (which is q , D ,) to r , and from r , drawing r, p , making with q, r , an angle of 42 , and then drawing a, p , that will be the vanishing line sought. To find the center C , and distance C, D^2 , of this vanishing line, draw a, D^2 , and find the other vanishing points of an equilateral triangle, as was done on the first vanishing line, a, b, c , viz. here, n , and o ; now draw $n, 4$, and $o, 3$, cutting $n, 4$, in 5 , which determines the face $3, 4, 5$.

Then find, in the same manner, the vanishing line c, k, i , for the face $4, 2, 11$, with this difference, that, as the former a, n, o , was taken below the first vanishing line a, b, c , because the face $3, 4, 5$, comes forward, with respect to $3, 4, 2$, this falls backward, with respect to the same face, and must therefore be drawn above a, b, c ; and having found the vanishing points, as in the others, draw $2, i$, and $4, k$, cutting $2, i$, in 11 , which finishes this face.

Then through b , the vanishing point of the side $3, 2$, find another vanishing line e, b, f , for the face $3, 2, 10$, and in it the points e , and f , as in the former vanishing lines, and draw $e, 2$, and $3, f$, cutting it in 10 , which finishes the face $3, 2, 10$, as the line D, a , (perpendicular to b, D ,) goes beyond the picture, take S, d , a fourth of S, D , and draw a parallel to D, a , and proceed as if this 4th was the whole distance, till you find the vanishing line; then from b draw a parallel to the vanishing line, which parallel will be that sought. The perpendicular is taken downwards, viz. a, f .

Through e , the vanishing point of $2, 10$; find another vanishing line; but as e, b, f , (in which is the point e ,) does not pass through S , draw e, S , and proceed on it as before, on the vanishing line a, b, c , which will produce the vanishing line e, g, h , for the face $2, 10, 12$, which is determined, by drawing $10, g$, and $2, h$, cutting $10, g$, in 12 ; and now join $12, 11$, which finishes another face, $2, 12, 11$.

Then through f , the vanishing point of the side $3, 10$, find one more vanishing line, f, l, m , for the face $3, 10, 1$, by the same process, as the last; and, having found the vanishing points, draw $m, 3$, and $l, 10$, cutting $m, 3$, in 1 , which finishes that face.

Then

Fig. 51. N^o 2.

Fig. 51. N^o 1.

Then draw from *l*, through *11*, for the side *11, 6*, is parallel to *1, 10*; draw *5, g*, cutting *11, 6*, in *6*; then *e, 6*, and *5, b*, cutting *e, 6*, in *7*, which finishes the face *5, 6, 7*, opposite, and parallel to *2, 10, 12*; join *6, 4*, this determines the face *4, 5, 6*, (which, here, happens to fall in one line) and also the face *4, 6, 11*.

Draw *6, f*, and *7, b*, cutting *6, f*, in *8*, which finishes the face *6, 7, 8*, opposite and parallel to *2, 3, 10*.

Draw *a, 8*, and *7, c*, cutting *a, 8*, in *9*, which determines the upper face opposite and parallel to *2, 3, 4*; join *9, 10,—9, 1,—9, 12,—8, 11*, and *8, 12,—5, 1*, and *7, 1*, which finishes the forwardest face, *1, 5, 7*, and completes the whole figure.

2, 3, 4, and *7, 8, 9*, being opposite and parallel, their vanishing line is the same, viz. *a, b, c*.

3, 4, 5, and *8, 9, 12*, being opposite and parallel, their common vanishing line is *a, n, o*.

2, 4, 11, and *1, 7, 9*, being opposite and parallel, their common vanishing line is *c, k, i*.

2, 3, 10, and *6, 7, 8*, being opposite and parallel, their common vanishing line is *e, b, f*.

2, 10, 12, and *5, 6, 7*, being opposite and parallel, their common vanishing line is *e, g, b*.

3, 1, 10, and *6, 8, 11*, being opposite and parallel, their common vanishing line is *f, l, m*.

Fig. I. Below is a representation of the same solid, projected without any other vanishing line than that of the horizon, and also without ichnography, or orthography, any farther than the geometrical draught of a decagon, or double pentagon *A*, and the axis of the solid marked *o, 1, 2, 3*, which axis is divided by taking *o, 1*, equal to a side of the decagon, *1, 2*, equal to radius (or a side of the hexagon), and *2, 3*, equal to *o, 1*, in which division the middle part *1, 2*, with either end, will be in extreme and mean proportion. Prop. 9. Book 13. Euclid.

N.B. A line is said to be cut in extreme and mean proportion, when the whole is to the greater segment, as the greater segment is to the less. Def. 3. Book 6. Euclid.

First draw the axis perpendicular to the horizon, and mark the divisions; then through 1, and 2, draw transverse lines, (*i. e.*) parallel to the horizon, and on them mark the length c, b , on one side, and c, a , on the other, but contrariwise; then set off the distance on the horizontal line, from S , the center of it, to d , and from d , draw through each extremity of the transverse lines, cutting the axis; and the points in which that is cut will determine the depth of each pentagon; the pricked line passing through 2, is so divided. The side $b, 2$, towards d , being equal to b, c , in the plan, and the side $2, a$, equal to c, a , and the line drawn through 1, contrariwise, (*i. e.*) c, a , towards d , and c, b , on the opposite side; draw d, a , cutting the axis in g , and d, b , cutting it in k ; after which, find the vanishing points of the sides of the pentagon, 4, 5, 6, 7, by drawing from D , (below) $D, 4$,— $D, 5$, &c. making 4, $D, 5$, an angle of 36 degrees, and the same angle with 5, $D, 6$, and 6, $D, 7$, which are all the vanishing points necessary: then, parallel to the horizontal line, draw b, i , through k , the point in which d, b , intersects the axis, and draw 6, g , and 5, g , cutting b, i , in b , and i ; then $b, 5$, and $i, 6$: lastly, 4, g , and 7, g , cutting $i, 6$, in b , and $b, 5$, in a , which finishes the lower pentagon. The upper pentagon is determined in the same manner, and by the same points, with this only difference, that the operation is reversed, in order to produce a contrary position. After which the whole icosaedron is completed, by joining the respective points of the two pentagons, and drawing from the same points to the two poles of the axis. All which may be performed with less trouble, and in less time, than is requisite to form the geometrical ichnography, and orthography. Here is added another on the side, projected by the same points, only instead of drawing d, b , cutting the axis (as in the former) a pricked line is drawn through the axis from S , which being cut, from d , (the distance) through b , finds k , the middle of b, i , and from d , to a , finds g , and so for the upper pentagon.

Fig. K. In order to represent this figure, by the same method, on an inclined plane; Draw the vanishing line of such plane C, E , and from S , draw S, D , parallel to it; join C, D , and make D, P , perpendicular

to

to it: draw at pleasure P, G, B; draw B, *f*, parallel to D, P, and equal to *o*, 3, the axis at figure A, which divide in 1, and 2, according to the geometrical proportion; then from D, draw to those divisions, cutting B, G; these interfections determine the axis according to the perspective proportion. Draw from C, lines through the two intermediate points of B, G; and, in order to find their respective lengths, set them off geometrically on C, D, from D, to *b*, and to *a*; that is, make D, *b*, equal to *c*, *b*, and D, *a*, equal to *c*, *a*; and on D, P, set off D, *b*, equal to *o*, 1; then drawing *b*, *a*, and D, *a*, parallel to it, *a*, will be a vanishing point (in the vanishing line P, S, C,) from which the axis, and transverse line, will be divided in the proportion of D, *b*, to D, *a*; wherefore, by drawing *a*, G, and *a*, B, the two transverse lines will be cut, the lower backwards, the upper forwards; in that proportion. D, *g*, is equal to D, *b*; so that drawing *g*, *b*; and D, *m*, parallel to it, *m*, will be the vanishing point dividing the same axis, and transverse lines, in the proportion of D, *g*, to D, *b*; wherefore draw *m*, G, and *m*, B, which will cut the transverse lines on the opposite sides in this last proportion.

This is the preparatory work for the figure K, which is projected upon it, as on a skeleton, all the lines corresponding, as appears on inspection; and all the rest of the operation is the same as at figure I.

Fig. L. This method is an universal one; (*i. e.*) the solid in any situation may be projected by it, and is perhaps the shortest of all.—For let any face be given, 2, 3, 4, and through any angle of that face, find the axis of the solid; divide that axis, perspective, in the two points, serving for centers of the two pentagons; complete those pentagons in the manner before taught, which, with the two poles of the axis, are all the points; and these being joined, the whole figure is formed.

It will be proper to draw (somewhere apart) the geometrical proportion of the axis, with its divisions, and the angles made by the planes; (*e. g.*) draw *q*, *g*, for the axis; divide it in *y*, and *z*, the centers of the two pentagons; and through *z*, draw, at right angles, *k*, *z*; make *z*, *k*, equal to the shorter side of the diameter of a

pentagon; draw k, g ; then z, k, g , will be the angle made by the interfection of the plane of the lower pentagon, with a face of the solid, terminating at the lower pole g , and consequently z, g, k , will be the angle made by the axis with that face, g, k .

Having given the face 2, 3, 4, with its vanishing line, distance, and points, find the vanishing line b, p , of planes perpendicular to c , the vanishing point of 4, 2, (one side of that face); and at x , the distance of this vanishing line b, p , draw x, p , making the angle a, x, p , equal to z, k, g ; draw c, p , which will be the vanishing line of the planes of the lower and upper pentagon (2, 4, 5, 1, 10, being the lower) of which one side is 4, 2; and by means of that side, with the vanishing line c, p , that pentagon is finished. Now find b , the vanishing point of lines perpendicular to the vanishing line c, p , and draw $3, b$, which will be the indefinite axis of the icosaedron; bisect the angle e, d, f , to p^* ; draw $p, 1$, cutting 4, 2, in l , and $l, 1$, will be the diameter of this pentagon, whose center is determined by the interfection of its diameter with the axis, and from that center to 3, will be the perspective representation of z, g ; wherefore from 3, draw a line in any convenient direction, so as not to interfere with the figure, as $3, o$, and parallel to it, b, d , equal to b, D^2 , the distance of b ; then draw from d , through the center, cutting $3, o$, in k ; this interfection will mark the place of the center of this lower pentagon, geometrically on $3, o$, by which measure the rest of the geometrical axis is divided, as appears above, at g, g , by means of parallels from y, z , and g . Now draw from the divisions of $3, o$, to d , cutting the axis in the upper center and pole; from p , draw through the upper center, and make that part of the upper diameter, from the center to 11, equal to the lower, from

* *N. B.* This bisection is made to find the vanishing point p , from which a line (drawn to 1,) will divide 4, 2, in half, and so become the diameter of the lower pentagon; for e , is the vanishing point of 4, 1, which is parallel to 2, 10; and f , of 2, 1, which is parallel to 4, 5. The same point p , might also have been found, by drawing d, p , perpendicular to d, c , for c is the vanishing point of the line 4, 2. Or as p , is in the plane of the vanishing line c, e , and also in that of b, p , it must be in their interfection, and therefore is found, as here, in the interfection of these two vanishing lines.

the center to 1, by drawing from 1, through the upper center to b, p , (the vanishing line of the plane passing through the axis,) cutting it in i ; then drawing from i , to the lower center, cutting the upper diameter in 11, which will be the angle of the upper pentagon over the middle of the side 4, 2, of the lower pentagon; and, in the same manner, find the other part of the upper diameter; that is, from the upper center, through l , the middle of 4, 2, draw to the same vanishing line b, p , and from the point of intersection *, draw through the lower center, cutting the upper diameter in r , which will be the middle of 7, 9, the line of the upper pentagon, over the point 1, of the lower pentagon; draw from the vanishing point c , through r , which will produce the line 9, 7, indefinitely; draw from e , through 11, cutting that line in 9, and from f , through the same point 11, cutting it in 7, which determines the length of 7, 9; draw $g, 11$, and $e, 7$, which finds 6; then $f, 9$, and $c, 6$, cutting it in 12; draw 11, 12, which finishes this upper pentagon. Now draw from 6, 7, 9, 11, and 12, to 8, the upper pole; then join the corresponding points of the two pentagons, which completes the icosaedron.

* N. B. The line here directed to be drawn, is so nearly parallel to b, p , that the point of intersection falls at too great a distance to be conveniently used; yet being the same method by which the last point 11, (of the same diameter) was found, it was proper to direct it, as best, when the points fall within reach.

But an expedient may be used to find r , the other extremity of this upper diameter. From i , (in the line b, p .) draw one line through the center of that diameter, indefinitely, and another through 11, (the extremity already found); and, at any convenient distance, draw a line through them both, parallel to b, p , as L, w, I, x , cutting these lines in I , and w : now as $i, 11$, necessarily passes through the center of the lower pentagon, and $i, 1$, through one extremity of its diameter; draw also i, l , through the other extremity, cutting the same line L, w, I, x , in L ; by this means the proportion of the two parts of the diameter is found geometrically: therefore, in the line L, w, I, x , make I, x , equal to L, w , and draw i, x , which will cut the upper diameter in the point r .—*This is thus particularly explained for its general use.*

The FOURTH PART.

Fig. 52. **I**N this part it is proposed to exhibit several expedients to facilitate the practice; and first to divide a perspective line in any proportion.

Let it be required to divide A, B , whose vanishing point is V , into four equal parts. Draw V, d , in any direction, and of any length, and A, f , parallel to it; draw d, B , cutting A, f , in f ; divide A, f , into four equal parts, at c, d , and e ; draw d, c ,— d, d , and d, e , which will cut A, B , in C, D , and E , the points required.

If room be wanting, any nearer distance will answer the same purpose, as D : in this case, draw D, B , cutting A, f , in 4; and divide $A, 4$, in the same number of equal parts, at 1, 2, and 3; and draw $D, 1$,— $D, 2$, and $D, 3$, which will find the same points.

Again, at No. 2, V, D , is drawn in another direction; for it may be in any, at pleasure, provided A, f , be drawn parallel to it; and here it is required to divide A, B , into two equal parts only; therefore bisect A, f , in e , and draw D, e , cutting A, B , in E , the point sought. Or, if it be more convenient, draw V, d , and A, f , parallel to it; bisect A, f , in \mathcal{D} , and draw d, \mathcal{D} , which will cut A, B , in the same point E ; for the truth of the operation depends on the parallelism of the two lines, V, d , and A, f . And in all these cases, the lines from D , or d , to the several divisions of A, f , or A, f , represent parallels, therefore the lines A, B , must be divided as the originals.

If V, d , No. 1, be the true distance of the vanishing point V , and A , the intersection of the picture, by the original line; then A, c, d, e, f , are the true originals, or geometrical proportions; and therefore when it is required to find the original proportions of a perspective line, already divided, the true distance and intersection must

be taken.—But in order to find the perspective divisions on a line already projected, the above operations are equally true, whatever distance be taken; and although *A*, be not the intersection; for *A*, *B*, any part of a perspective line, will be truly divided by this method.

At No. 3. it is required to make a segment on the perspective line *A*, *V*, from the point *C*, towards *V*, equal to *A*, *B*, on the same line. Draw *D*, *C*, till it cuts *A*, *e*, in *c*; make *c*, *e*, equal to *A*, *b*, and draw *e*, *D*, cutting *A*, *V*, in *E*; then will *C*, *E*, be, perspective, equal to *A*, *B*.

Or, if it be required to make the perspective of a part equal to *b*, *A*, (on the original line;) at the distance of *c*, from *b*, divide the original line *A*, *e*, in the manner required, and draw *c*, *D*, and *e*, *D*, which will determine the part *C*, *E*; and so of any other proportions.

Fig. 53. No. 1. Here is an original plan, in its geometrical proportion, placed obliquely below the ground line; it is required to project it in perspective. Continue the several divisions to that line, and having found the two vanishing points *a*, and *b*, draw from those points to the several intersections, which will form the perspective representation; but as it often happens, that on one side there may not be room for many intersections, because they run much wider than on the other side, after having drawn one only, as to *c*, and drawn from thence to *b*, which finds the point *1*, take any other point between *b*, and *S*, as *B*, and draw from thence through *1*, cutting the ground line in *C*, and make use of the distance *a*, *C*, (instead of *a*, *c*;) setting that off, from *C*, to *f*, and from *f*, to *g*, &c. as often as necessary; and drawing from *f*, to *B*, and from *g*, to *B*, &c. the same points *2*, *3*, *4*, &c. will be found, as if there had been space to repeat the distance *c*, *a*, as many times; then draw *1*, *b*,—*2*, *b*,—*3*, *b*,—&c. which will complete the work.

Fig. 53. No. 2. The same thing is done without a geometrical plan: and here the measures of the original squares are set off equally on each side of *a*, as *1*, *2*, *3*, *4*, and the distances *b*, *D*, and *a*, *D*,
brought

brought down to the vanishing line at ϑ , and d ; and, after having drawn the two extreme lines a, o , and b, o , then drawing, respectively, $\vartheta, 1, —\vartheta, 2, —\vartheta, 3, —\vartheta, 4$, and $d, 1, —d, 2, —d, 3, —d, 4$, the points of the extreme lines b, o , and a, o , are found; from which points, on one side, drawing to a , and, on the other, to b , the plan is completed. And if room were wanting for S, D , above, the points b, a , and ϑ, d , might be found by means of d , below, making S, d , equal to the distance S, D .

Fig. 54. If it be required to find a segment of F, b ; from F , towards b , equal to A, B , of the line A, a , bring down a, D , the distance of the vanishing point a , to d ; draw d, B , cutting the ground line in e ; bring down also b, D , the distance of the vanishing point b , to d ; draw d, F , cutting the ground line in f ; make f, g , equal to A, e , and draw d, g , cutting F, b , in E ; then will E, F , represent an original line, equal to the original of A, B , and therefore will be equal, perspective, to A, B , which is all that is necessary to find the length F, E , perspective, equal to A, B . But as it is indifferent whether the ground line A, g , be used for this purpose, or any other parallel, and as some other is often more convenient, take any line parallel to the vanishing line, as $B, 6$, and draw d, A , cutting it in 4 , and d, F , cutting it in 6 ; then make $6, 5$, equal to $4, B$, and draw $d, 5$, which will cut F, b , in E . Or take any other parallel, as $1, F$; make $F, 3$, equal to $1, 2$, and draw $d, 3$, which finds the same point E : for d, A, e , and d, f, g , are equal triangles, being between the same parallels, and having equal bases; [Euclid, Book 3. Prop. 38] and $B, 6$, or $1, F$, being parallel to the same vanishing line a, d , will cut off equal triangles from e, d, A , and g, d, f ; therefore, &c.

Fig. 55. Another way of dividing perspective lines, is by marking the geometrical proportions on the rays, from D , as on $D, a, —D, b$, the rays of the vanishing points a , and b , of A, B , and A, G, F . Make $D, 1$, and $D, 2$, equal, and draw $D, 6$, parallel to $1, 2$; then a line from 6 , cutting A, b , and A, a , in any parts, will divide those two lines equally, as $6, G, B$, makes A, G , and A, B , perspective, equal. If

Fig. 50.

Fig. 50. N° 2.

Fig. 55. N° 4.

Fig. 55. N° 3.

Fig. 53. N^o 1.

Fig. 52. N^o 3.

Fig. 53. N^o 2.

If any other proportion be required, mark it on the ray of the line; for instance, $D, 3,$ is equal to $D, 1,$ and $\frac{1}{2}.$ Draw $D, 5,$ parallel to $1, 3;$ and draw $5, B,$ cutting $A, b,$ in $F;$ then $A, F,$ is in the same proportion to $A, B,$ as $D, 3,$ is to $D, 1.$

$A, c,$ is another perspective line; $D, c,$ its ray; and $c,$ its vanishing point; and $1, 4,$ divides $D, a,$ and $D, c,$ unequally; and $D, 6,$ being parallel to $1, 4,$ the line $6, E, B,$ divides $A, c,$ and $A, a,$ in $E,$ and $B,$ perspective, in the same proportion; $A, E,$ being to $A, B,$ perspective, as $D, 4,$ to $D, 1,$ geometrically.

Fig. 55. No. 2. This method may also be used in cases like that of 54. Let $E, F,$ be a perspective line, whose vanishing point is $a,$ it is required to make $A, B,$ (of another line) equal to $E, F.$ Draw from $A,$ to $a,$ the vanishing point of $E, F;$ and draw $A, E,$ cutting the vanishing line in $e;$ draw $e, F,$ cutting $A, a,$ in $C;$ then $A, E, F, C,$ will represent a parallelogram, whose opposite sides being parallel and equal, $A, C,$ must be equal to $E, F.$ Now make $D, 1,$ and $D, 2,$ equal; and draw $D, f,$ parallel to $1, 2;$ draw $f, C,$ cutting $A, b,$ in $B;$ then will $A, B,$ be equal to $A, C,$ (as by the last Figure;) but $A, C,$ is equal to $E, F;$ therefore $A, B,$ is also equal to $E, F;$ which was to be done.

Fig. 55. No. 3. $B, A,$ is given, it is required on $E, A,$ to make $A, C,$ equal to $B, A.$ Draw $4, 1,$ making $D, 4$ and $D, 1,$ equal; draw $D, 5,$ parallel to $4, 1;$ then draw $5, B,$ cutting $E, A,$ in $C,$ and $C, A,$ will be equal to $B, A;$ which was to be done.

But if $5,$ goes beyond the picture, divide $D, 4,$ in half, at $2;$ and draw $D, 3,$ parallel to $2, 1;$ then (having divided $A, B,$ perspective, in half at $6,)$ draw $3, 6,$ which will cut $E, A,$ in the same point $C.$

N. B. The manner of dividing a perspective line in half, is described at Fig. 52, No. 2.

Fig. 55. No. 4. Let the same things be given as before; but the distance $D,$ being beyond the picture, take a fourth (or any) part of

the distance at D ; then take a fourth of S, V , at E , and draw D, E , which will be parallel to V, D , which tends to the true distance; therefore the angle at D , will be the same as at D .—Draw c, d , making D, c , and D, d , in any proportion required, and D, e , parallel to c, d ; set off S, e , four times to F , and draw F, B , cutting S, A , in C : then will A, C , be to A, B , as D, d , is to D, c , (*i. e.*) in the proportion required.

N. B. Any line drawn from F , will cut the same lines in the same proportions, as F, f, b ; for A, b , is to A, f , as A, B , is to A, C ; (*i. e.*) as D, c , is to D, d .

Fig. 56. As this is the place allotted for expedients, the reader is referred back to Fig. 45, where the manner of finding, on the horizontal plane, the plans, or ichnographies, of cubes projected on oblique planes, is described. The letters, constantly used, shew the situation in general; but here is a difficulty peculiar to this position, which is, that the side a, b , is exactly in front, and, for that reason, it is impossible to find the feat, or ichnography of the point a , without some expedient; therefore draw a, a , and b, b , both parallel to the horizontal line; draw at pleasure from S , (which is the vanishing point P , brought up to the horizontal line), cutting b, b , in b ; draw P, b , cutting a, a , in a ; draw a, C , perpendicular to the horizontal line, cutting S, b , in C ; draw C, A , parallel to b, b ; then A , will be the point sought, viz. the feat of a , on the horizontal plane, by which the feat, or plan of the upper square is found on that plane.

Fig. 57. No. 1. At Fig. 31, are several lines tending to a point beyond the limits of the picture, and there, as well as elsewhere, the reader is referred to this place for expedients in such cases; which frequently happen, especially when the distance of the picture is considerable. The present figure shews the manner of drawing lines to an inaccessible point. Suppose A, B , and C, D , two lines, tending to such point, beyond the picture; it is required to draw from g , a line, tending to the same point. Draw N, O , through g , in any direction, and B, D , parallel to it, at any convenient distance, within the picture; at D , with the compasses, set off the length of N, O , as D, E ;

so that E, intersects the line A, B; divide D, E, in F, making D, F, equal to O, g; draw F, f, parallel to A, B, cutting B, D, in f; then draw g, f, which will tend to the same point with A, B, and C, D; for B, D, is divided in f, in the same proportion as D, E, is divided in F, (*i. e.*) as N, O, in g, (Prop. 2. Book 6. Eucl.) Let there be another point, from which it is also required to draw to the same inaccessible point, whether between the lines A, B, and C, D, or without, as here at *b*; which, if it be so situated, as that a line N, O, may conveniently be drawn to it through g; then draw N, g, O, *b*, and take the distance O, *b*, and add it to the line E, D, from D, to I; and draw I, *i*, parallel to f, F, cutting B, D, in *i*, and drawing *b*, *i*, it will tend to the same point; for the triangle D, I, *i*, is similar to D, F, f; and therefore D, *i*, is to D, I, as D, f, to D, F; and, consequently, D, *i*, to O, *b*, as D, f, to O, g.

Let it also be required to draw from *k*, to the same point. Draw 1, 2, through *k*, parallel to B, D; set off 1, 2, from f, to 3; divide f, 3, in 4, as 1, 2, in *k*; draw 4, 5, parallel to A, B; and then drawing *k*, 5, it will tend to the same point.—Here g, f, is used instead of C, D, as more convenient; for any two lines tending to the same point, will answer the purpose.

Fig. 57. No. 2. Another method is proposed: let A, B, and C, D, be two lines tending to a point, beyond the picture; now, in order to draw from *e*, to the same point, draw any line through *e*, cutting these two lines in A, and C; and at any convenient distance B, D, parallel to A, C, draw A, D, and (parallel to D, C,) draw B, *b*, cutting A, D, in *b*; then draw *b*, *d*, parallel to B, D, and consequently equal to it; draw *e*, D, cutting *b*, *d*, in F, which divides *b*, *d*, in the same proportion as A, C, is divided by *e*; wherefore set off *d*, F, to D, *f*, or (which is the same thing) draw F, *f*, parallel to *d*, D, and drawing *e*, *f*, it will tend to the point required.

By the same process, *m*, *p*, is found, tending to the same point, viz. draw *m*, *n*, parallel to A, C; draw *n*, D, cutting B, *b*, in *s*;

draw s, t , parallel to B, D ; draw m, D , cutting it in t ; then set off s, t , from B , to p ; and drawing m, p , it will tend to the same point.—The only requisite is to find the same proportions on the line B, D , as on A, C , or on B, p , as on n, m .

Fig. 57. No. 3. Now, on these principles, suppose S, f , the horizontal line, (or the vanishing line of any other plane,) S, D , the distance, D, b , a parallel to an original line, tending to a vanishing point beyond the picture; it is required to draw from a , to the same vanishing point.—Draw a, d , and b, e , both parallel to S, D ; continue b, D , till it cuts a, d , in d ; draw b, g , parallel to S, f ; draw d, g , cutting S, f , in i ; draw a, i , cutting D, S , (continued) in b ; set off g, b , from b , to e , (or S, b , from f , to e), or draw b, e , parallel to S, f ; then drawing a, e , it will tend to the vanishing point required.—It is evident, that b, f , might have been set off from S , to g , instead of drawing the parallel b, g ; or that a parallel to S, f , from b , would have determined e , as well as setting off S, b , at f, e , &c.

Fig. 57. No. 4. Let a, b , and C, d , be two lines, tending to a vanishing point; if there are any number to be drawn to the same point in the same line, as 1, 2, and 3, draw a, c , parallel to a, C , at any convenient distance; then draw from $C, 1, 2$, and 3 , parallels to a, a , cutting a, c ; then from c , and the other intersections of a, c , draw to O , any point in a, b , and through 7, the intersection of c, O , with C, d , draw 7, 8, another parallel to a, c ; then from 1, 2, and 3, draw through the respective intersections of the line 7, 8, viz. 1, 4,—2, 5, and 3, 6, which will be the lines required, all tending to the same vanishing point.

Fig. 58. No. 1. Suppose A, B , a perspective line, to be divided in any proportion, but its vanishing point to be beyond the picture; continue D, S , to A, B , cutting it in e ; draw at pleasure e, i ; set off B, g , from e , to b ; draw S, b , and D, i , parallel to it; set off b, i , from g , to l , upwards; draw D, l , and A, M , parallel to it. (By this means, e, i , will be divided proportionally to D, e , (*i. e.*) e, b , to e, S , as b, i , to S, D ; and g, l will be to g, B ,

as

Fig. 57. N. 1.

Fig. 57. N. 3.

Fig. 57. N. 2.

Fig. 57. N. 4.

Fig. 58. N. 1.

Fig. 58. N. 2.

as S, D, to S, *e*, which is the proportion wanted.) Now A, M, will be the original of A, B; therefore, on it, make the geometrical divisions required; draw from these divisions to D, which will cut A, B, perspectively.

N. B. If D, *l*, had been already drawn (as well as A, B,) then only draw A, M, parallel to it, and proceed as above.

Fig. 58. No. 2. After *e*, *i*, is divided, if room be deficient below for A, M, draw *n*, *p*, (from *p*, the extremity of the picture) parallel to D, *l*, and bring down *n*, to *q*; (*i. e.*) make *p*, *q*, equal to *p*, *n*; then draw from D, parallel to *n*, *q*, which finds *r*, the distance of the vanishing point of A, B; then make the geometrical division on A, *c*, as *a*, *b*, *c*, from which points draw to *r*, and the lines *a*, *r*, *b*, *r*, and *c*, *r*, will cut A, B, in the same points.

Fig. 59. No. 1. Let E, F, be given, and the direction of E, G, drawn at pleasure, in order to form either a cube, or any other cubical figure, of known measures, (the horizontal line, with its distance, being always supposed to be given, or known). Continue the side E, G, till it meets the horizontal line in *a*, which will be its vanishing point; draw *a*, D, and D, *b*, perpendicular to it, cutting the horizontal line in *b*; draw E, *b*; then E, *g*, parallel to D, *a*, and E, *h*, parallel to D, *b*; and make these two lines of the geometrical lengths required (as here they are both equal to E, F): draw *g*, D, cutting E, *a*, in G, and *h*, D, cutting E, *b*, in H; by which operation those lengths are determined: draw G, *b*, and H, *a*, which finish the lower square or plan: raise perpendiculars at G, and H, and the remaining angle; and draw F, *a*,—F, *b*, cutting the perpendiculars at G, and H, in I, and K: lastly, draw I, *b*, and K, *a*, which completes the cube.

Fig. 59. No. 2. If room be wanting, below, for the lines E, *g*, and E, *h*, they may be drawn parallel to the horizontal line, as in this scheme; but then the distance *b*, D, must be brought down to *d*, and drawing *d*, *g*, will find the same point G, in the line E, *b*, as by the above operation; and the distance *a*, D, must also be brought down to *d*, from whence, drawing to *b*, the point H, will be found. The rest is as No 1.

Fig.

Fig. 59. No. 3. Is an expedient, in case the point a , is beyond the picture. Continue the line G, E , whose direction is given as before, indefinitely towards D ; and set off the distance of the picture S, D , from S , to D , the point where that distance cuts G, E , continued. From O , in the horizontal line, at the extremity of the picture, draw a parallel to G, E, D , cutting S, D , in d ; transpose S, d , to d , on the line S, D ; draw d, O , and D, a , parallel to it, which will tend to the true vanishing point a , beyond the picture. Now proceed, as at No. 1, or No. 2; and having drawn E, b , and found the points G , and H , and drawn G, b , bisect the angle a, D, b , to c ; draw c, E , cutting G, b , in L ; draw L, H ; then raise the several perpendiculars at G, L , and H ; draw F, b , cutting H, K , in K , and c, F , cutting L, M , in M ; draw b, M , cutting G, I , in I ; join F, I , and M, K , which completes the whole. If a parallel to S, D , be drawn from O , cutting the line D, E, G , in a , then O, a , will be equal to O, a , (so that if a, O , and a, O , were both raised up perpendicular to the picture, and also D, S , and D, S , on S ; then a , would coincide with a , and D , with D ;) by which means the lines O, d , and O, d , may both be spared.

The same figure is repeated several times, on purpose to shew by what various means the same effect may be produced; but if the lines of the three operations were crowded together in one scheme, they could scarce be separated by the eye or understanding, so as to discover what was peculiarly, and distinctly essential to each.

If they appear to be somewhat intricate, it must be considered, that they are to be used on extraordinary occasions only, and may be always avoided, if the artist chuses rather to take sufficient room on another scale, than confine himself to the space which happens to be left in his picture.

Fig. 60. Let A, C , be a perspective line; it is required to find the geometrical length of a part, as A, B . If its distance C, D , be within the picture, and room to set it off on the vanishing line, transpose that distance from C, D , to E ; draw E, B , cutting the ground

Fig. 59-N^o2.

Fig. 59-N^o1.

Fig. 60.

Fig. 59-N^o3.

ground line in F; then A, F, is the geometrical length sought.—But if D be out of the picture, take any portion of S, D, as here S, *d*, a fourth, and S, *c*, a fourth of S, C; draw *c*, *d*, which will be a fourth of C, D; transpose *c*, *d*, from C, to *e*, and draw *e*, B, cutting A, F, in *f*; then A, *f*, will be a fourth of A, F, the geometrical length sought.—It is evident, that the same expedient will serve to find any proportion of A, C; for suppose it had been required to cut off the geometrical length A, F, thereon, this is only reversing the operation, (*i. e.*) drawing E, F, cutting A, C, in B; or, if room be wanting, drawing *e*, *f*, which finds the same point B.

Fig. 61. No. 1. In order to find the vanishing line of a plane making a given angle with another vanishing line, it has been taught to find, first, the vanishing line of planes at right angles with both, on which to measure the angle of inclination. Now suppose Q, S, B, the vanishing line given; it is required to find the vanishing line of planes, making a certain angle therewith, and passing through B, their common intersection. To this end, find Q, the vanishing point of lines perpendicular to B; draw Q, P, perpendicular to Q, B, which will be the vanishing line, perpendicular to both planes; set off its distance to *d*; draw *d*, P, making Q, *d*, P, the angle of inclination; and, lastly, draw B, P, which will be the vanishing line sought. But if room be wanting, above, for the distance S, D, divide S, B, in half, at *b*, and take S, *D*, half of S, D, and find *q*, the vanishing point of perpendiculars to *b*; draw *q*, *p*, perpendicular to *q*, B; set off the distance of *q*, to *r*; and draw *r*, *p*, making *q*, *r*, *p*, the angle of inclination: draw *b*, *p*, which would be the vanishing line sought, if half the distance was the true distance. Now, therefore, from B, draw a parallel to *b*, *p*, which parallel will be the vanishing line sought.

Fig. 61. No. 2. Let it be required to draw a line through B, S, at the point A, in any angle, perspective, as (*e. g.*) 45 degrees; this is done by making the same angle at D, drawing D, *d*, and then *d*, A, which is the line sought. But if room be wanting, take S, *d*, the half of the true distance (or any less proportion, as may be necessary;) make

make the same angle at d ; draw d, D ; then divide S, A , in half, at a ; draw D, a ; and, lastly, draw through A, a , parallel to D, a , which will be the line required.

Fig. 62. When the parallel D, C , of any line b, a , runs out of the picture, before it reaches the vanishing line, any other line, within the picture, will answer the purpose, as D, c , by drawing from a, b , and f , parallels to it, cutting the ground line in e, g , and h , from which, severally, drawing to c , the perspective points of a, b , and f , are found in the position required.

Fig. 63. No. 1. The center and distance of the picture being given, let B, A , be an original line, in any direction (*e. g.*) inclined to the picture in the angle B, A, B ; and, cutting it in A , (A, B , being its feat, or orthographic projection on the picture) it is required to find the perspective length of A, B . Draw S, V , parallel to that feat, and S, D , perpendicular to it, and equal to the distance; draw D, V , parallel to the original A, B ; draw A, V ; then V , is the vanishing point, and A, V , the indefinite perspective representation. And the length of A, B , is determined, by drawing B, D , cutting A, V , in b . Or setting off the distance V, D , to d , and A, B , to B , and drawing B, d , finds the same point b .

This is the most general scheme for the purpose, because the angle of incidence is, at once, referred to the picture, without regard to any other plane, and so the original line may have any inclination, without making the least difference in the operation, on account of the position of the picture.

But another example or two, with additional circumstances, may farther illustrate this kind of operation.

Fig. 63. No. 2. A, B , is an original line; A, a , its feat on the picture; A, b , the perspective of A, B , found as in the former; B, a , (parallel to S, D ,) its feat on the ground; a, b , the perspective of that feat, found by drawing a, S ; for if D, S , be turned forward on the point S , and B, a , turned backward on the point a , till both are perpendicular to the picture, it is evident that b , will be the perspective of B , and, consequently, a, b , of a, B .

Fig. 61. N^o 2.

Fig. 61. N^o 1.

Fig. 62.

Fig. 63 N^o 1.

Fig. 63. No. 3. A, B , is an original line; A , its interfection with the picture; A, a , its feat on the picture; V , its vanishing point, found as at No. 1; and A, b , its perspective, which is all that is necessary: but besides, let it be required to find its feat on the ground, in the direction of the original line; (*i. e.*) supposing a plane passing through it, and its feat on the picture. Draw B, a , parallel to S, D , which will be that feat; for, turning the triangle S, D, V , forwards on S, V , and the triangle A, B, a , backwards on A, a , till both are perpendicular to the picture, the plane A, B, a , will cut the picture in the line A, a , and the ground, in the line B, a .

And to explain it still farther, a, B , is turned round on a , to a, B , supposed perpendicular to the picture, and lying on the horizon; A, a , drawn on the picture perpendicular to the horizon; and to these is also joined the line B, a , which is the true geometrical feat of the original A, B , (perpendicularly) on the ground; as B, a , is its feat in the direction of the original line, a , and a , being their interfections with the picture. The perspective of a, B , is a, b , for S , must be its vanishing point by construction, D, S , being parallel to B, a . And the perspective of a, B , is a, b , drawn to v , its vanishing point, which is found by drawing a perpendicular from V , to the horizontal line: for the geometrical line a, B , being on the ground, perpendicularly under the original line A, B , its vanishing point must necessarily be on the horizontal line, perpendicular to V , the vanishing point of A, B ; wherefore a, b , drawn towards v , is the perspective of a, B . To make this (if possible) more clear, S, d , is drawn perpendicular to the horizon, and equal to S, D , (the distance); and d, v , drawn parallel to a, B , which finds the same vanishing point v .

These circumstances are thus minutely explained on this, and other occasions, that the universality of the principles may appear in their application to the various cases that occur, or may be required.

Fig. 64. Let A, B , be given as the side of a square to be projected, space being deficient every way; draw A, S , and B, S ; and from any convenient portion of A, S , or B, S , (as here a 4th,) draw
M b, f ,

b, f , parallel to A, B ; then take the same portion of the distance, (*i. e.*) a 4th, as S, D ; draw f, D , and D, g , at right angles to it; draw g, b , and so finish the small square, a, b, e, c , by the usual method:—then the large square is completed, by drawing parallels to the sides of the former, as B, E , parallel to b, e ; A, C , parallel to a, c ; B, C , parallel to a, c, b , for the diagonal; and lastly, C, E , parallel to c, e .

Or, instead of B, C , parallel to b, c ,— S, c , continued, will find the point C ; or S, e , continued, will find the point E ; either of which is sufficient for the purpose.

This may not be an improper place to decide a question much debated, viz. Whether the representation of a long wall, on a picture parallel to it, should be made of the same height, at the utmost extent, as directly opposite to the eye, since it appears of less height the farther it is extended? To which question, the answer is, that the wall should be drawn of equal height, how far soever extended; because the representation will appear as much less, in proportion, at the extent, as the original appears.

Fig. 65. Let A, B, C, E , be the original wall; D , the eye of the spectator; and, consequently, A, D, B, D, C, D , and E, D , visual rays; and a, b, c, e , the representation on a parallel plane; the triangles A, D, B , and a, D, b , are similar, as are the triangles C, D, E , and c, D, e ; and the lines A, C, B, E , and a, c, b, e , are all parallel, as are also a, b , and A, B , and c, e , to C, E : therefore c, e , must be equal to a, b , which was to be proved; and in like manner, and for the same reasons, 2, b , and e, a , are equal, being the representations of the equal lines 1, B , and $E, 3$, made equal to A, B , and C, E . See Euclid, Book I. Prop. 37, 38, 39, &c.

Of the same nature is that other question, Whether, in representing a row of columns, standing on a line parallel to the picture, those, which are more distant from the center of such picture, should be made equal to, or less, or bigger than the nearer? It is allowed they appear less; but the answer to this question is, that they ought (in this situation of the picture)

Fig. 48. N^o. 2.

picture) to be made bigger; and, though so painted, will really appear as much less, in the painting, as they appear in nature.

Fig. 66. Let A, B, and C, be the plans of three columns, either square or round; and first suppose them square; it is evident, that the representation of them will take up the space marked by the visual rays, from the extreme angles to D, the spectator's eye, on the parallel picture, whose section is S, *k*; (*i. e.*) the representation of A, will fill the space S, *f*; that of B, will fill the space *g*, *b*; and that of C, the space *i*, *k*.

If the columns are round, the several spaces, which are filled by their representations, will be determined by the pricked rays, cutting the line S, *k*, which spaces are marked by small arches.

But if the picture be placed on the line S, 2, the representations of the round columns will be equal to each other, or nearly so. And if on the line S, 3, or any other between 2, and D, (the end S, remaining unmoved) the representations of the more distant columns will then, indeed, be in less spaces of the picture, by certain proportions, according to their several distances.—But on all these pictures, they will be truly represented, and will equally exhibit the images of the originals to the eye of the spectator at D, who will necessarily form the same ideas of the proportions, and distances of the objects, from any one of these pictures, as from any other of them; which may all be considered as transparent planes, or as one such plane, moveable on a hinge at S, from *k*, to 2, or 3; which plane no more hinders the spectator from discerning the original objects, than the common medium of air; and as all the visual rays are necessarily right lines, the picture, or medium, makes no alteration in their directions, which are continued, without interruption, from the several parts of the originals, to D, through any one of these transparent planes, and whichsoever be chosen, the representations can be determined by nothing but the intersections of those visual rays with such plane, and cannot possibly be false, if these intersections are truly found.

N. B. The rays for the round columns are determined, by making tangents to the several circles from D; and the

points, in which they touch, are found, by bisecting the line from *D*, to the center of each circle, as *D*, 5, for the circle *C*; and with the length 4—5, as radius, making an arc through the center, cutting the circumference in the points sought.

If the circles were nearer each other, and *D* at a greater distance, the difference would be proportionally less, and at a sufficient distance, not at all offensive; as indeed nothing, that is truly represented, can be; but even at this, or any distance, the rule (being demonstrably just) cannot vary, and therefore must be universal.

Fig. 67. No. 1. The usual points and lines being given, it is required to represent a door open at any angle. Let *l*, *c*, be the side given, on which it is supposed to turn; *S*, *b*, the side of the room on the floor; make *S*, *D*, *a*, equal to the angle required; draw *a*, *c*, cutting the ground line in *i*; then *i*, *c*, *b*, will represent the same angle: and, for the breadth of the door, draw *i*, *g*, parallel to *D*, *a*, and *D*, *c*, cutting it in *g*; from *g*, to *k*, set off the geometrical breadth, and draw *D*, *k*, cutting *c*, *i*, in *e*; then will *c*, *e*, be the perspective breadth sought, equal to *g*, *k*.—Now, for the thickness, draw *D*, *b*, perpendicular to *a*, *D*; and draw *b*, *e*, to *b*, which will be the direction of the edge; draw *b*, *k*, *f*, which will be parallel to *D*, *b*; and make *k*, *f*, of the thickness required; draw *f*, *D*, which will determine the thickness, perspective; or, instead of drawing *b*, *k*, and *D*, *f*, continue *g*, *k*, to *i*, on the ground line, and a parallel from *f*, to the same; and, from those intersections, draw to *a*, which will give the thickness of the door; draw *e*, *m*, parallel to *c*, *l*, and *a*, *l*, cutting it in *m*; and draw *b*, *m*, which finishes the door. Or, as

Fig. 67. No. 2. Instead of drawing *i*, *g*, and *b*, *k*, below the ground line (in order to determine the breadth and thickness of the door), bring down the distance *a*, *D*, to *d*, and draw *d*, *c*, cutting the ground line in *g*; and make *g*, *k*, equal (geometrically) to the breadth; draw *d*, *k*, cutting *a*, *c*, in *e*, which finds the perspective breadth: then, for the thickness of the edge, bring down, in like manner,

Fig. 65.

Fig. 66.

manner, b , D , to d , and draw d , e , cutting the ground line in o ; make o , f , equal to the thickness, and draw f , d ; all the rest is as the former:

N. B. If the door be shut, the point e , (at No. 1.) will touch E ; and m , will touch M . Or again,

Fig. 67. No. 3. For the breadth, draw the pricked line c , l , parallel to the horizontal line, and equal to one third of c , l , the height (which is here the geometrical breadth,) and D , 1 , parallel to it, of any length; draw 1 , 2 , cutting D , 1 , and D , a , equally, in 1 , and 2 , and D , 3 , parallel to 1 , 2 ; and draw 3 , 4 , which will cut a , c , in e ; then e , c , will be the perspective breadth. This method has been before explained at Fig. 55; No. 1, and 2, and is, in many cases, very expedient. The thickness is found as in the two former; and the perspective direction is determined by the lines b , e , and b , m .

N. B. The point e , which determines the breadth of the door; may be any where in the pricked semicircle, if the angle of the aperture be not particularly required:

Fig. 68. Having a square e , h , g , f , given, to make, on it, an octagon, draw a , b , through the center, perspective parallel to the sides e , g , and h , f ; (*i. e.*) from their vanishing point; and c , d , also, through the center, at right angles to a , b , perspective; then draw D , Æ , making an angle of $67\frac{1}{2}$ degrees with S , D , (which is the geometrical angle that e , a , makes with a , b); and, then, from Æ , draw to e , cutting a , b , in a , which is one of the angles; and from the same point Æ , through h , cutting d , c , in c , another angle; and again to g , cutting c , d , in d ; and also through f , cutting a , b , in b , which determines the last angle; e , a ,— c , h ,— g , d ,—and h , f , being all parallel; and, lastly, join e , e ,— c , g ,— g , b ,— f , d ,— d , b , and h , a , which completes the octagon.

This is done in less time than described, for all the four points wanting, are found without once moving the end of the ruler from Æ .

If the picture will not admit the length S , Æ , then, instead of the angle S , D , Æ , of $67\frac{1}{2}$, make S , D , B , an angle of $22\frac{1}{2}$, which

which (being the complement of $67\frac{1}{2}$ to 90) is the geometrical angle that c, a , makes with e, b ; and from B, draw through e , which will cut c, d , in c ; and from the same point B, to f , cutting c, d , in d ; and through b , cutting a, b , in b ; and, lastly, through a , to g , cutting a, b , in a ; by which means all the same points are found, and the octagon completed, by joining the rest.

The other octagon (of pricked lines) is formed by the same vanishing points.

Fig. 69. No. 1. In order to represent a cornice, first draw the geometrical elevation only, as here for the Doric, in pricked lines; then draw lines from S, through every angle of the projection, as 1, 2, 3, &c. and draw from D, through A, meeting the line S, 1, in a ; and so on, from D, through every intersection of the line A, B, as D, 4, meeting the line S, 2, in o , and D, 5, meeting the line S, 3, in p , &c. by which operation the whole cornice is completed without any geometrical plan.

The reason of this proceeding will appear on inspection of the square $6, a, 1, A$, which is the square of the whole projection, and of which A, a , is the diagonal, issuing from the corner, or angle of the wall.

And when it is necessary to determine an outer angle at the extremity, make there a square corresponding to the above, as 11, 7, 8, 9, which is easily done, by means of the lines already found; and to determine the mouldings of this angle, perpendiculars must be raised from those of the first, already completed, to the diagonal A, a ; and from the several intersections, lines drawn to S, will cut the diagonal 11, 8, of this square; from which intersections, dropping perpendiculars, these, meeting the several members, will determine the mouldings of this last angle. For instance, from the point p , raise a perpendicular to q , in the diagonal A, a ; and from q , draw to S, cutting the diagonal 11, 8, in r ; from r , drop a perpendicular, meeting the ray p, S , in t ; which is the point sought; and so of the rest.

N. B. The

N. B. The second diagonal *11*, 8, is that issuing from the corner of the wall, in this place; and is parallel (in the geometrical) to 6, 1, in the former square; and the reason for using these different diagonals, is that *A*, *a*, projects obliquely forwards, and *11*, 8, projects at right angles to it, or obliquely backwards.

Fig. 69. No. 2. The operation is, here, for an inner angle, exactly the same as in the former, for an outer angle, to the determination of the outlines of the mouldings inclusive; after which, the difference is, that from *a*, and the rest of the projections (in the former) the line *a*, 6, with those under it, are parallels; whereas, in this latter, they are all rays from *S*; and the line *a*, 8, with those under it, in the former are rays, but in this latter are parallels.

Fig. 69. No. 3. Omitting the geometrical elevation, only knowing the measures; let it be required to project the cornice (for instance, of the Ionic order) immediately on a given part of the picture, without raising it higher (as in the former example). Draw *A*, *B*, for the uppermost line; and from *B*, to *A*, (the geometrical projection of the whole cornice) set off the several parts of that projection; draw from *B*, to *d*, the distance, brought down to the horizontal line, and from *A*, to *C*, the center, cutting *B*, *d*, in *a*; then *a*, *B*, will be the perspective diagonal of the cornice. Now draw from all the divisions between *A*, and *B*, to *C*, cutting the diagonal *a*, *B*; and, from all these intersections, drop perpendiculars, and another perpendicular also from *B*; and, on this last, mark the several geometrical heights of the members; and from these points, draw to *d*, cutting all the perpendiculars, and their respective intersections will determine the perspective projections of all the members, by which the cornice will be completed; (*e. g.*) *e*, *C*, cuts the diagonal in *f*, and *e*, *d*, cuts the perpendicular *f*, *E*, in *E*, which determines the projection of that member, and so of the rest.—The points of the projection being thus found, may serve either for an outer angle, (as here,) or for an inner angle, (as in the last example,) the perspective extremities remaining the same. And if an inner angle be required from any other point

point in B, C, as G, draw G, *d*, cutting A, C, in *k*; then G, *k*, will be (perspectively) parallel to B, *a*, and, consequently, will represent the diagonal, by which such inner angle may be completed, as the outer was by means of B, *a*.

Fig. 69. No. 4. When it is required to project a cornice (as here of the Corinthian order) not parallel to the picture, from a point given, as B; draw first the geometrical diagonal of the projection B, A, parallel to the horizontal line, and mark on it the angular projections of the several members; and having bisected the right angle d, D, *d*, and continued the line of bisection to *o*, in the horizontal line, and brought down the distance *o*, D, from D, to $D\frac{1}{2}$, draw B, *o*, and A, $D\frac{1}{2}$, cutting it in *a*; then B, *a*, will be the perspective diagonal. Now draw from all the divisions of A, B, to $D\frac{1}{2}$, cutting B, *a*, in the several perspective points of the diagonal, from which drop perpendiculars, as also one from B; and, on this last, mark the geometrical heights of the several members; and, from all these points, draw to *o*, cutting their correspondent perpendiculars, which intersections will determine the angular points of the cornice; and drawing lines from every one of these angular points, to the vanishing points d, and *d*, the cornice is, thus far, completed.

And, for the inner angle H, draw H, *o*, and *a*, *d*, cutting it in *b*, which gives this diagonal; and divide it, by drawing from the several divisions on B, *a*, to *d*; then dropping perpendiculars, from the points thus found, in H, *b*, they will meet their respective corresponding lines (already drawn) from the perspective angular points of the outer angle B, to *d*, and these last intersections will determine this inner angle.

The same operation determines the outer angle G, with these only differences, that the diagonal of this last is not parallel, but perpendicular to the two former, (*as was particularly explained at the N. B. of No. 1, with respect to that Doric cornice*); and the lines run to the opposite vanishing point d.

N. B. *The manner of finding the shadows of these cornices is explained in the SUPPLEMENT.*

Fig. 69. N^o 1.

Fig. 69. N^o 3.

Ionic.

Fig. 69. N^o 2.

Fig. 69. N^o 4.

Corinthian.

Fig. 69. No. 5. In this, and the following figures, the skeleton, or case only, of the whole cornice, is projected in straight lines, that the reason of the operation may appear more simply and clearly, unembarrassed with that number of points, and lines, which are necessary in determining minutely each member.

The center and distance being given, as usual, draw first the square A, B, E, F, for the breadth of the solid; then draw A, C, and D, E, cutting it in G; draw G, H, parallel to A, E, and draw E, C, cutting it in H, which will give the cubical perspective of the solid; produce B, A, to I, making A, I, equal to A, E, for the projection of the whole cornice, (which, in four of the orders, is equal to the height, according to most architects; (*i. e.*) in all but the Doric); draw C, I, and 3, E, cutting it in K; and 1, H, cutting the same line C, I, in L; then draw 2, F; and lastly draw K, M, (parallel to A, B,) cutting 2, F, in M, which completes the figure.

N. B. A, E, is the height of the cornice; and A, K, is the diagonal of its projection.

Besides that the pricked lines, within, shew the conformity of this operation to the former figures, let it be considered that the triangle K, A, E, represents the angular projection of the whole cornice; for 3, 4, is the vanishing line of the plane of that triangle, and 3, the vanishing point of K, E; as the triangle L, H, G, represents another projection of the cornice (the plane of which is perpendicular to K, A, E,) whose vanishing line is therefore 1, 2, and the vanishing point of H, L, is 1. The other angles are determined in the same manner; for 1, 2, is also the vanishing line of the triangle M, B, F, it being in the same plane as L, G, H, and 2, the vanishing point of F, M; so is also 4, 3, the vanishing line of P, N, O, this triangle being in the same plane with K, A, E; and 4, is the vanishing point of O, P.

1, C, 3, is also the vanishing line of the plane K, L, H, E; for 1, 3, and C, are all vanishing points in this line: 2, 3, is the vanishing line of the plane K, E, F, M; and 1, 4, is the vanishing line of the plane L, H, P, O; and 4, C, 2, is the vanishing line

of the plane M, P, F, O; for 4, 2, and C, are all in this line, &c.
 Fig. 69. No. 6. If the cornice be Doric, as that projects more, in proportion to its height, than the other orders, all the difference is in taking A, *e*, instead of A, E, with its correspondent measures, &c. which will necessarily give 3, 2, in this scheme, for a vanishing line, instead of 3, 2, (at No. 5.) and 1, 4, instead of 1, 4; the rest of the operation being the same as above.

N. B. In this figure, the plane M, *p*, *f*, *o*, happens to fall in the vanishing line 4, C, 2.

Fig. 69. No. 7. This figure (which is seen by the angle) cannot need much explanation, after what has been already said; the lines *e*, *f*, and *g*, *b*, being (with *e*, *g*, and *f*, *b*;) in a plane parallel to the picture, have no vanishing points; *a*, *b*, has *o*, for its vanishing point; and *i*, *k*, has *p*: for as this vanishing line *o*, *p*, passes through the center of the picture, the distances C, *o*, and C, *p*, are to C, *d*, (the distance of this vanishing line) as the side of a square to its diagonal; by which means the height and projection of the cornice keep their proportions, the angular projection being to the height, as the diagonal of a square to its side, in the four orders, which have their heights and projections equal. Hence it is evident, on inspection, that the perspective angle *b*, *a*, *q*, (or C, *a*, *o*;) represents the geometrical angle C, *d*, *o*, as *s*, *k*, *i*, (or C, *k*, *p*;) does C, *d*, *p*.

Fig. 69. No. 8. This figure differs from the last, only, in its being obliquely situated to the plane of the picture in every respect, the last having the lines *e*, *g*, and *f*, *b*, parallel to it.

The scheme sufficiently shews the operation, on the principles so often explained; the letters *a*, *e*, *g*, and *k*, mark the angles of the cornice, as in the former; and *o*, is the vanishing point of *a*, *b*, found by making *o*, $\frac{1}{2}$, as the side of a square, to $\frac{1}{2}$, *y*, the diagonal, (which $\frac{1}{2}$, *y*, is equal to $\frac{1}{2}$, D, the bisection of the angle E, D, F,) for this is the proportion of *q*, *b*, to *q*, *a*. E, *o*, is the vanishing line of the plane *a*, *e*, *f*, *b*; and F, *o*, the vanishing line of the plane *a*, *g*, *b*, *b*.

Fig. 69. N^o 8.

The FIFTH PART.

O F S H A D O W S .

THAT part of perspective, which relates to the projection of shadows, is less necessary, than any of the preceding parts, and is wholly omitted by *Pozzo*, in his treatises on the subject, though one of the greatest masters in the executive part, and who seems to have done every thing else by rule.

However, it was thought proper to give a few examples, not only of cases that most commonly occur, in the course of practice, but also of some others less usual, and more difficult, to shew the application of these principles to this purpose, as well as to correct the mistakes of some writers on the subject.

Fig. 70. No. 1. In this scheme, the light is supposed to come from the sun, which being considered as at an infinite distance, the rays are treated as parallel; but it does not follow, that therefore the shadows must be represented parallel, except in one case, (and that very rare,) which is, when the rays are parallel to the picture; an instance or two of which shall be first given.

The rays of light are here supposed to come from the sun, and are not only parallel among themselves, but also to the picture, and therefore the most simple, and most easy to project. Any one ray, as *f, g*, being drawn in the direction required, all the rest must be parallel to it. Draw from *F*, the bottom of the line *f, F*, a parallel to the horizontal line, meeting *f, g*, in *g*, which determines that shadow; for *g*, is the shadow of *f*, on the ground, and *F, g*, of the perpendicular line *F, f*; and so for each perpendicular line, as, for *b, i*, draw *b, H*, parallel to *f, g*; and *i, H*, parallel to the horizontal line, meeting in *H*; and *k, K*, parallel to *f, g*; and, lastly, *l, K*, parallel to the horizontal line, meeting in *K*; and the same operation for the open door, which completes the whole.

N. B. If one only of the points g , or H , had been found, the other would be determined, by drawing through that, already found, to S , the vanishing point of i , F , which is perspectively parallel to H , g , &c.—for H , g , the shadow of b , f , is parallel to it in the original, and therefore both run to the same vanishing point S .

Fig. 70. No. 2. This figure, though two walls only, is exhibited, to shew the manner of determining the shadow on a plane standing obliquely to the horizontal line. Having drawn B, E , parallel to A, b , the direction of the rays, as in the former, and G, E , parallel to the horizontal line, meeting it in E , G, E , will be the shadow of G, B ; but as it is interrupted by the wall C, L , raise a perpendicular at L , (where G, E , cuts the bottom of that wall) and draw A, C , cutting it in e ; then C, e , will be the shadow of the line B, C , on the plane C, L ; for, all the rays are parallel to A, b , and b, A , is the vanishing point of B, C , therefore A, b , is the vanishing line of the plane made by the rays which pass through the line B, C ; and (a, A , being the vanishing line of the wall C, L ,) A , is the vanishing point of the common intersection of the two planes, whose vanishing lines are b, A , and a, A ; therefore A , is the vanishing point of the shadow C, e , of the line B, C , on the wall C, L .

If the reader finds any difficulty in conceiving this, let him imagine the wall C, L , continued to its vanishing line a, A , and the plane of rays to its vanishing line b, A , these planes will then intersect at A ; and as both planes pass through the eye, so also must their intersection, which will be a line from the eye terminating in A .—It cannot be forgot, that all lines, drawn from the same vanishing point, are, perspectively, parallels; (*i. e.* represent lines geometrically parallel;) wherefore if D , were brought forwards on S , perpendicular to the picture, it would represent the eye, and D, A , the intersection sought. Now A, C, e , represents a parallel to D, A , in this situation of D .

The point e , however, might have been determined by the line B, E , intersecting the perpendicular from L , in this particular case, as the wall breaks the shadow G, E , in L ; but, otherwise, the general rule is as above.

Fig.

Fig. 70. No. 3. Is the same subject, with this only difference, that the wall C, L, is shorter, on which account, the shadow G, E, of B, G, is thrown, wholly, on this side of it, so that the line G, L, E, cannot intersect the bottom; which disposition is chosen, on purpose to shew the use of the vanishing point A, in determining the direction of the shadow on the wall C, L, as explained above.

Though this also might have been found, by continuing the line N, L, till it cuts G, E, in L, and there raising a perpendicular, meeting the ray B, E, in *e*, and then drawing C, *e*.—But instead of all this work for the direction of one line, nothing more is necessary, than drawing from A, through C, as has been explained.

If the line *a*, N, L, be continued, and the ray A, *c*, till they meet in *E*; and the parallel *E*, G, be drawn, and also the line *b*, N, G, till it meets *E*, G, in *G*; and the perpendicular *G*, B, be raised, and *b*, *c*, B, continued, till it meets *B*; and the ray B, *E*, be drawn parallel to A, *b*; then the shadows (represented by *c*, *e*, and G, E,) brought down to G, E, will unite in *E*, and, by that means, illustrate the whole operation,

Fig. 71. No. 1. Here, though the shadows are geometrically parallel among themselves, they are, nevertheless, oblique with respect to the picture (as is generally the case); and, for this reason, the shadows will all tend to the same vanishing point in the horizontal line.

U, is the vanishing point of the rays of light, found by drawing from the eye, to the picture, in the direction chosen, or given, for that purpose. To conceive this, suppose *D*, S, raised up, on S, till perpendicular to the picture: in that situation, *D*, U, is the parallel of the rays, cutting the picture in U, which is therefore the vanishing point of them.

And raising a perpendicular from U, to the horizontal line, cutting it in V, that will be the vanishing point of all the shadows, cast on the plane of the horizon, by all objects perpendicular to that plane; so that the shadow of any point is found, by drawing first from such point to U; and then from the seat of the same point to V: *for instance*, from the point *b*, (of the object A,) draw to U; and again from B,
the

the feat of b , draw to V , cutting b , V , in b ; this will be the shadow of b , on the ground, and B, b , will be the shadow of the whole line b , B : in like manner, drawing c , U , and C, V , cutting it in e , that is the shadow of c ; and thus is also found f , the shadow of f : after which, by joining all these points, is completed the whole shadow of the object A , on the ground.

For the shadow of the octaedron, the several points of it marked 1, 2, 3, 4, are all found in the same manner, viz. by drawing from the several angles to U , and from their feats respectively to V , each angle, feat, and shadow, being marked by the same character; for instance, 2, the angle on the body of the octaedron; 2, its feat perpendicularly under it; and 2, its shadow; and so of the rest. Thus also may be found the shadow of any object not perpendicular, by finding the perpendicular feats of the principal points, and using such feats, and points, as perpendicular lines; (*e. g.*) having found g , the feat of E , draw E, U , and g, V , intersecting in b , that will be the shadow of E ; and drawing b, G , is determined the whole shadow, on the ground, of the pole G, E .

But for those shadows, which fall on planes not horizontal, some other expedients are to be used, as that of A , on the parallelopiped H . Having first found the shadow on the horizontal plane, raise two perpendiculars where that shadow touches the edge, (as at i , and k), to l , and m ; and since the upper side is parallel to the horizon, draw from l , and m , to the same vanishing point V , which determines it: so also is found the shadow of the cube on the bottom of the parallelopiped A , first drawing a perpendicular from n , upwards (where the shadow on the ground cuts the line n, B), and determining the top of that perpendicular w , by the line o, U ; then for the point p , continue V, f , backwards, till it cuts q, S , in r ; at r , raise a perpendicular to t ; draw t, U , which finds the point p ; and, lastly, draw p, w , which finishes that shadow. Or if B, n , be continued backwards, till it meets q, S , as in x , and a perpendicular be there raised, cutting the line o, S , in y , a line drawn from y , to w , will find the shadow p, w .

N. B. This

Fig. 70. N°1.

Fig. 70. N°2.

Fig. 70. N°3.

E. G.

N. B. This line y, p, w , runs not to any vanishing point, because it is parallel to the picture.

The shadow, on the ground, of the plank, that rests upon the cube, is found by dropping a perpendicular from the point, where it touches the edge, to the ground; and drawing from the top to U , and from the bottom to V , is found one point on the ground, which is sufficient. For, drawing from N , through that point, to the horizontal line, is found the vanishing point M , of the shadow on the ground; to which vanishing point, draw from the other corner of the plank, which rests on the ground, and one line more (from the top of the plank to U ,) completes this shadow, supposing the whole of it on the ground: that part of it, on the upper face of the cube, is found, by drawing from the points, where the plank touches it, to the same vanishing point M ; and that other part, on the front of the cube, by continuing the line, of the bottom of the cube, from q , through the shadow on the ground to z ; then drawing from the points in which the plank touches to z , and \dagger . The reason of this operation is obvious; for, supposing the front of the cube to extend beyond z , the shadow of the ground would there meet it, and that part of the shadow, on this face, must be between the points in which the plank touches the cube, and the ground at \dagger, z .

Here are added four perpendicular posts, on the same line, to shew, that though the shadows of them are geometrically parallel, yet as they are not cast in a direction parallel to the picture, (in which case they would be parallel, and equal, in perspective,) they must, in this direction of the light, have all the same vanishing point V , and, therefore, cannot be parallel in their representations, nor of equal lengths, though they are all of the same height, or depth, on the picture, from the front line on which the posts stand.

The error of making the shadows parallel, in this case, is to be observed in the Jesuit's Perspective. The author might possibly be misled, by considering, that as the sun is so large a body, and so distant, the rays of light from thence descend in parallel lines, or (which is the same thing) in lines not to be distinguished from parallel;

parallel; but he should also have considered, that all parallel lines, not parallel to the picture, will, on the picture, have a common vanishing point, to which they mutually tend, as the present case requires, and which makes so great a difference in the representation. For all lines, in perspective, are supposed to pass through the eye of the spectator, and to meet the plane of the picture somewhere (except those which are parallel to that plane); and the point wherein any line, so passing through the eye, intersects the plane of the picture, will be the vanishing point of all other lines parallel to that line.

This is the very construction of a vanishing point, on which almost the whole practice of perspective depends.

N. B. In the Jesuit's Perspective, the 3d edition, translated by Chambers, 1743, page 132, the second example is false, as the extreme lines of the shadow (though cast forwards) are made geometrically parallel, which should run to a vanishing point in the horizontal line, and would then represent parallels; and, in the text, the reader is instructed in this false method. Page 133, false, inasmuch as all the lines, at the feet of objects, (*i. e.*) the direction of the shadow which ought to run to a vanishing point to represent parallels, are made geometrically parallel to H, K, L, and the reader is instructed so to make them. Page 134, is right, where the sun is directly behind; and he is right also, where the sun is supposed to cast the shadows parallel to the picture; but he is false in every oblique direction, which directions are much more frequent than any others. These errors are plainly owing to his not understanding (or not considering) the necessity, and use of vanishing points; perhaps he was sensible of the difficulty of oblique directions, which seems to be the reason that, for five pages together, all the shadows are cast in the same direction, (*i. e.*) all of them parallel to the picture; so that they afford no variety, except of the objects; that is, no variety of instruction, or any cases that
need

need it. His shadows, from artificial lights, are true; but no difficult or intricate cases are given, either of objects placed obliquely, or shadows thrown on planes oblique to each other; but all on planes parallel, or at right angles to each other.

And most of the mistakes into which many painters, and writers on this subject, have fallen, (who perhaps may not have been altogether deficient in science) are owing to the attention to objects, as they appear generally in nature, without referring their appearances to the eye of a spectator fixed to a point, or without sufficiently considering what kind of images such appearances, in nature, must necessarily form, on a transparent plane, between the eye and object, in every different direction.

It was said above, that by drawing a perpendicular from U, to V, this last would be the vanishing point of the shadows of all lines perpendicular to the horizontal plane; and also, that the shadows of any other lines (not perpendicular) might be determined, by finding the seats of any points on the ground, and drawing from such points to U, and from their seats to V; and thus was found *b*, the shadow of E, and the whole shadow of the octaedron, and other objects.

But to shew the extensive use of vanishing points, here is added another method for oblique lines: 7, 8, is a post inclined to the horizon, but parallel to the picture. Draw from U, a parallel to 7, 8, cutting the horizontal line in *u*, which will be the vanishing point of the shadow of 7, 8, on the ground; draw 8, U, and 7, *u*, cutting it in 9; then 7, 9, is that shadow, without farther operation: and if there were many lines in the same direction, that is, parallel to 7, 8, it might be worth while to find their common vanishing point *u*, to which all their shadows would tend; but, otherwise, it may be determined by the vanishing point V; for dropping a perpendicular from 8, to 10, this will be its seat; wherefore, having drawn 8, U, as before, draw 10, V, which finds the same point 9; then drawing 7, 9, that will find the same shadow.

The reader will observe, that the post 7, 8, though not perpendicular to the horizontal plane, is, however, parallel to the picture;

and in case of any obliquity in an object, if still parallel to the picture, a line, as U, u , drawn parallel to such obliquity, will always truly find u , the vanishing point of the shadow. For the triangles $u, 9, U$, and $8, 9, 7$, are similar, as well as the triangles $V, 9, U$, and $8, 9, 10$; and the line $8, 9, U$, is common to both pair of triangles; therefore it must be divided in the same point 9 , by either of the correspondent lines $7, u$, or $10, V$.

But when the original is not only oblique to the horizon, but also to the picture (as the post $11, 12$); then the vanishing point of such oblique line must be found by means of a scheme like that at Fig. 63, which (if understood) will render this intelligible. Or the vanishing point of $11, 12$, for instance, which is such an oblique line, and whose seat is $13, 12$, may be found, by continuing the line $13, 12$, to its vanishing point S ; thence dropping a perpendicular; and, lastly, continuing the projected line $11, 12$, till it cuts that perpendicular in Θ , which is the vanishing point sought. This post leans forwards, in an angle of 65 , marked at D ; (*i. e.*) the angle S, D, Θ , and whose vanishing point being Θ , below; thence draw through U , till it cuts the horizontal line, which intersection will be the vanishing point of the shadow; and having drawn $11, U$, (as in all the former cases) draw from 12 , to that vanishing point, cutting $11, U$, in 14 , and then $12, 14$, will be the shadow sought. To shew that this shadow is truly found, draw from 13 , the seat of 11 , to V , which will cut $11, V$, in the same point 14 , and is a proof.

N. B. When the vanishing point is first given, then the seat is found by drawing a perpendicular from Θ , to the horizontal line, cutting it, as in S ; then drawing $S, 12$, and a perpendicular from 11 , cutting it in 13 .

And this will be general, for any line, viz. to draw from its vanishing point, through the vanishing point of the ray of light, to the vanishing line of the plane on which the shadow is to be projected, whether it be the horizontal plane, or any other; and this intersection, with the vanishing line of the plane on which the shadow is cast, will be the vanishing point of the shadow. For (in this scheme) imagine

the plane D, S, Θ , raised on S, Θ , till D, S , be perpendicular to the picture; then a line D, U , determines the vanishing point of the rays; and, consequently, a line through Θ , and U , to the vanishing line of the horizon, will give the vanishing line of the plane of rays passing over the whole line $\Theta, 12, 11$, and therefore, also, the vanishing point of the shadow $12, 14$. See this farther explained in the SUPPLEMENT.

Fig. 71. No. 2. Is a cube on an inclined plane; a, S, b , is the vanishing line of that plane, W , is the vanishing point of the lines 1, 2,—3, 4,—5, 6, and 7, 8; wherefore, having given U^2 , for the vanishing point of the rays, draw from W , through U^2 , to V^2 , (in the vanishing line a, S, b ;) and then, drawing from 3, 5, and 7, to U^2 , and from 4, 6, and 8, to V^2 , the shadows of 3, 5, and 7, are determined, which are all the points necessary for completing the whole shadow.

Fig. 71. No. 3. In this scheme the object is (as the last) on an inclined plane, and the sun obliquely behind the object; on which account U , the vanishing point of the rays, will be above V , the vanishing point of the shadows; for it is to be always remembered, that every vanishing point is formed by a line passing through the eye parallel to the original; and wheresoever such line cuts the plane of the picture, that intersection is the point sought. Now if the sun be beyond the object, a parallel to its rays will, necessarily, cut the picture somewhere above; and as S , is the center of the picture, and S, D , its distance, imagine D, S , raised on S , perpendicular to the picture; in that situation, D, U , is the parallel to the rays (whose direction is supposed to be given); therefore U , is the vanishing point of those rays; and as P , is the vanishing point (which will be perspectively perpendicular to the vanishing line a, C, b , and) of 1, P , and all its parallels, draw U, P , cutting the line a, C, b , in V , and that will be the vanishing point of all the shadows; wherefore, drawing $U, 1, U, 2, U, 3$, and then from V , through the seat of each line, the points 1, 2, and 3, of the shadow, are found.

Fig. 71. No. 4. In order to shew the conformity of operation, here is added the same figure, with similar circumstances, on the plane of the

horizon. U, V , is, in this scheme, therefore, *geometrically* perpendicular to the vanishing line a, S, b , and parallel to the lines $1, p, — 2, p, — 3, p$, whose shadows are sought. The rest needs no explanation.

N. B. In this, and all the former, after having drawn $U, 1$, or any one of the rays, and V, P , intersecting it in 1 , all the other points of the shadow may be found, by only drawing through the bottoms, or seats, of the remaining lines from V , and then drawing to the vanishing points a , and b , of the figure, which will find the points 2 , and 3 , as $1, a$, finds 2 , and $2, b$, finds 3 , &c.

Fig. 71. No. 5. Here is once more the same object, with the sun behind it; V , the vanishing point of the shadows coinciding with S ; U , the vanishing point of the rays perpendicularly above it. Having drawn $U, 1$, and V, a , cutting it in 2 , the rest is determined as in the *N. B.* of the last, viz. by means of the vanishing points a , and b ; and as the cube is a little oblique before S , the ray $U, 1, 2$, determines the plane of 2 , by which the whole is completed, as has been explained. But if the cube had been directly before S , it would have been very difficult; or if the object had been a single line, as $4, 7$, it would have been impossible, without an expedient; because the ray $U, 6$, and the line of the shadow $V, 7$, coincide; in which case, draw $V, 8$, at pleasure, and from 7 , draw a parallel to a, S, b , cutting it in 8 ; draw $8, 9$, parallel to $7, 4$, and equal to it; draw $U, 9$, cutting $V, 8$, in 3 ; lastly, draw $3, 6$, parallel to $8, 7$, which determines the point 6 .

Fig. 72. No. 1. In this scheme, the light O , is supposed that of a candle, or other luminous point, whence it is diffused every way as from a center; its foot, on the ground, is F . In order to find the shadow of the door b, e, h , draw F, b , cutting S, H , in g ; there raise a perpendicular, and draw O, e , cutting it in c ; then b, g , will be the shadow on the ground, and g, c , on the side of the room; and to find the direction of c, f , as a is the vanishing point of the top and bottom of the door, draw a, b, H , cutting S, H ,

Fig. 71 N^o. 1.

Fig. 71 N^o. 2.

S, H, in H; and then H, will be the intersection of the plane of the door with the plane on which this part of the shadow is cast; draw H, *i*, parallel to *b, e*, and *a, b, e*, cutting it in *i*, which will be the point wherein the line *a, b, e*, meets the same plane; wherefore draw *i, c*, which will be the direction, sought, of the shadow *c, f*; lastly, draw *f, b*, which completes the whole shadow.

It is evident, that if the plane of the door was continued, it would meet the side of the room in H, *i*; and the point *c*, having been found by the perpendicular *g, c*, the direction of the shadow, passing through *c*, must be *i, c, f*.

Or the shadow *b, f, c*, might be found by a method more geometrical, thus.

Fig. 72. No. 2. Having drawn F, *b, g*, (as before) and the perpendicular *g, c*; and also having drawn *a, b, H*, and the perpendicular H, *i*, and *a, b, e*, cutting it in *i*; and found the vanishing line *a, k*, of the plane of rays passing through the line *a, b, e, i*; from *k*, the intersection of this vanishing line with S, *k*, the vanishing line of the side of the room (on which part of the shadow is cast) draw *k, i*, cutting *g, c*, in *c*, and the angle of the room in *f*; and draw *b, f*, which finishes the shadow.

N. B. The vanishing line *a, k*, is found, by drawing a line through *a*, parallel to Θ, m ; for Θ, m , represents a ray parallel to the picture, found by drawing F, *l*, parallel to the horizontal line, and *l, m*, perpendicular to it, cutting *a, b, e*, in *m*; and then, drawing Θ, m .

Or (without using the vanishing line *a, k*,) draw Θ, a , and F, *a*, raising a perpendicular at the intersection of it, with the edge of the room, cutting Θ, a , in *o*, which will be the foot of the light on the side of the room; and Θ, o , will be perspectively in the direction of (or parallel to) *e, b*; wherefore draw *o, b, f*, &c.

This is farther explained in the several manners following, because many such cases happen, and the understanding this, fully, may be of great use. *a, b*, continued, cuts the side of the room in H, and

a per-

a perpendicular being raised at H, and a, b, e , continued, they meet in i .—So that if the plane of the door was continued, H, i , would be the extreme edge, touching both that side, and the floor of the room, and could have no shadow, either on the side, or *below*; but, in that case, there would be a shadow *above*; because f , is the angle of the room, and b, f , being in a plane parallel to the picture, and f, i , in a plane perpendicular to it, the whole shadow would be the triangle b, f, i ; for Θ, F, l, m , is a plane parallel to the picture, and m, e, b, a , the edge of the top of the door, continued to the horizon at a ; therefore Θ, m , (being parallel to the picture) may be considered as the intersection of the plane of rays, passing over the top of the door; and, consequently, a, k , (parallel to it, passing through the eye, and cutting the picture) is the vanishing line of that plane; and, cutting S, k , the vanishing line of the side of the room, on which part of the shadow is cast, k , will be the vanishing point of the intersection of those two planes, viz. of the rays, and side of the room; wherefore, drawing k, i , this line determines the shadow c, f , and drawing b, f , the whole is determined.

Or drawing b, f , parallel to a, k , meeting the angle of the room, that will determine the point f , by which f, c , is found; for the plane of the rays is parallel to a, k , and b, f , is parallel to the picture, and is intersected by the plane which generates the vanishing line a, k ; as a, k , is the vanishing line of the plane of rays passing through the line a, b, e, i ; and o, b, f , being the intersection of that plane, with the plane on which that part of the shadow is cast, b, f , must be parallel to a, k . Again, o , is the seat of the light on the plane of the shadow, and b , is the seat of e, b , on the same plane; therefore b, f , the shadow of e, b , must be the continuation of the line o, b ; and that line is necessarily parallel to a, k , (by construction) because the plane of this part of the shadow is parallel to the picture; and the plane Θ, m, i, k, a , cuts both the plane of the picture in a, k , and that which receives the shadow in o, b, f , which two latter are parallel planes.

The other door l, q, k , in No. 1, is opened at right angles,
and,

and, consequently, S , is the vanishing point of the top and bottom. Draw F, k , cutting the side of the room in m ; raise a perpendicular m, n ; draw O, l , cutting m, n , in n ; then draw S, n , cutting the angle of the room in p ; and join p, q , which finishes the shadow. Or q, p , might have been first found thus: Draw O, S , and, in that line, find t , by a perpendicular from the intersection of F, S , with the bottom of the room, which point t , is the seat of O , on the plane p, q , that is, the farther side of the room; and drawing t, q, p , that will be the direction of the shadow, on this plane; and draw S, p , and O, l , meeting in n .

The two square blocks, A , and B , against the wall, are introduced to shew the course of the shadows, which need little explanation; only it is to be observed, that t , being the foot of the light on the wall, is to be used, on that plane, as F , on the floor. Thus draw from t , through all the points which touch the wall, to the beginning of the ceiling, and through those intersections (with the edge, or angle of the ceiling) draw from S ; then from O , draw through the projecting angles, of each block, lines meeting all those rays from S , and the several points of the shadow, on the ceiling, are terminated:

The shadow of the hollow square C , is found in the same manner, only remembering, that as t , represents the foot (of the light) on the wall, and as the depth of the hollow is to be regarded in casting the shadow, so the foot must be as low as that depth, which is found by drawing from the top of one of the lines, viz. 1 , to t , and a parallel to it from the bottom of the same line 2 , cutting O, S , in V , which will be the foot of the light for this hollow; then drawing $V, 2$, and $O, 1$, meeting in 3 , draw from 3 , a line parallel to $1, 2$, which will give the indefinite shadow of $1, 2$, in the bottom; and draw from 1 , meeting that line where it intersects the angle of the upper side; and one more line from O , through 2 , cutting the parallel from 3 , which gives the determinate shadow of 2 , and completes the whole. Or the shadow of the line $2, 1$, (on the upper plane of the square hollow) may be found, by means of the foot of the light on that plane, thus. Continue the line from 1 , parallel to the-

the horizontal line, and continue the perpendicular from t , till that cuts it; then draw a line from S , through that intersection, and a perpendicular from O , cutting it; and from this last intersection (which is the foot of the light) through r , draw the shadow sought, and a line from O , through z , determines the length of it.

Then, for the shadow of the ladder, draw from its vanishing point 4 , through O , and from S , through F , meeting in G ; draw from G , through each foot of the ladder, to the intersection of the floor with the farther side of the room continued, cutting it in 5 , and 6 ; then, where G , F , S , cuts the same line of intersection (as at 7), raise a perpendicular, cutting G , O , 4 , in A , and draw A , 5 , and A , 6 , which lines will cut the top of the ladder, and (having before drawn G , 5 , and G , 6 .) by these means the whole shadow is found from G , to 5 , and 6 , on the floor, and from A , to 5 , and 6 , on the wall, supposing no other object to intervene.

For G , O , 4 , is the line in which all the plane of rays must pass to the two sides of the ladder G , 4 , representing a line parallel to them, passing through the light O , and touching the ground in G , and the wall in A .

But as G , 5 , and G , 6 , meet the other side of the room in 9 , and 10 , draw from these last points to 4 , which will determine that part of the shadow, and would meet A , 6 , and A , 5 , in their intersections with the angle of the room, if there were no door, or if the door were shut.

Again, as the door will also receive part of the shadow, draw from 11 , and 12 , (where G , 5 , and G , 6 , meet a , H , the intersection of the plane of the door) to 13 , and 14 , where A , 6 , and A , 5 , intersect the edge of the door, which completes the whole shadow. Or the vanishing points of these two lines 11 , 13 , and 12 , 14 , may be found, by raising a perpendicular at a , which perpendicular will be the vanishing line of the plane of the door; and from F , and G , (both in the horizontal line) drawing F , 4 , and G , 4 , cutting that vanishing line, in their respective vanishing points f , and g ; and then drawing f , 14 , and g , 13 , is found the shadow on the door.

N. B. *This is farther explained in the SUPPLEMENT.*

The shadow of the table on the ground is determined, by drawing lines from F, the foot of the light, through each angle of the table, on the ground; and then drawing from the light, itself, through all the upper angles, meeting those lines from F, respectively. And for that part of the shadow on the door, continue the line of the bottom of the door k, w , till it meets F, x , as in y ; at y , raise a perpendicular, cutting O, x , in L; draw L, S, which determines the shadow on the door, and completes the whole.

The shadows of the windows are found, in a like manner; for instance, the window E. Find the foot of the light on the plane E, which is to receive the shadow, thus: Draw a parallel from F, cutting the side of the room, 15, continuing the line F, 15, and find, there, the thickness or depth of the window 15, 16; draw O, 17, parallel to F, 16, and 16, 17, parallel to F, O; then 17, will be the foot of the light sought: draw 17, 18, and O, 19, cutting it in 20; from 20, raise a perpendicular, cutting the inner lines of the window, which determines the shadow; and so of the rest.—For the round window, the like method is used, the same point 17, being the foot of the light, for that whole plane; take two or three lines from the outer, to the inner circle, parallels to O, 17, and draw from 17, through the bottoms and from O, through the tops, and their several interfections will give the points of the shadows, &c. on the inner plane.

N. B. *At Fig. 72, No. 3, and 4, in the SUPPLEMENT, is the continuation, and conclusion of what relates to shadows.*

Of the images or reflections of objects in reflecting planes.

Fig. 73. **I**N this scheme are represented the reflections of several objects, in the water. Every object is seen as far, or deep within the reflecting plane, as it is placed without it. Thus, to find the reflection of the pile A, part of which is in the water, and the rest above the surface of it, measure from the top to that surface, and set off the same measure downwards to a .

But for the pile B, which inclines, the perpendicular height from the surface of the water must be taken. If it inclined so, as to continue still parallel to the plane of the picture, then a perpendicular from the top would touch the water at 2, in which case, B, 2, would be the measure to be taken downwards, and then the reflection would be equal to the representation of the object; and if it inclined inwards, so as that the top was perpendicularly over 1, then B, 1, would be that measure (shorter than the representation of the object); if forwards, so as to be perpendicularly over 3, then B, 3, is the measure, which is the measure here taken, and 3, 3, is the perpendicular depth of the reflection, which therefore makes the reflection longer than the representation of the object.

The principal difficulty, in most reflections, is to find the seat of the object on the surface of the reflecting plane; for when that is found, the reflection is made, by repeating that distance either geometrically, or perspectivevly, as the case may require, in, or on the reflecting plane: the block C, hangs over the water, and projects from the wharf, touching the edge of it, at the point 4; therefore measure from 4, to the surface of the water 5; then draw from S, (the vanishing point of the four sides of the block) through 5, and drop a perpendicular from its extreme angle, cutting S, 5, in 6, which is its seat on the surface of the water; and this measure repeated downwards, finds the reflection of that angle, by means of which the rest is easily determined. Or having first found the reflection of the edge of the wharf, by repeating the perpendicular 4, 5, downwards, to 7, draw a line from S, through 7, and a perpendicular, from the corner of the block, cutting that line, will find the same corner, or angle sought. The reflection C, is similar to its original, and all the rays run to S, as in the original.

The reflection of the block E, is found in the same manner; the vanishing point of E, is F, but the vanishing point of its tranverse sides is beyond the picture, to which the corresponding sides of the reflection, or image, is drawn, as well as those of the block itself: the piece E, hangs over the piece C, but makes so small an angle (with a per-

perpendicular from its interfection e ,) that it becomes necessary to use an expedient; therefore draw (from e ,) a line parallel to D, S , as e, f , and another from the edge, or corner, of the block, to g ; draw F, f, g , and drop perpendiculars from f , and g ; then measure from f , downwards, to the surface of the water b , and repeat that measure to i ; draw F, i , cutting the perpendicular from g , in k , and transfer i, k , backwards, by parallel lines, perpendicularly under E , which will determine the reflection I, K , by which the rest is completed; (*i. e.*) dropping perpendiculars from e , and the corner of E , the parallels from i , and k , will meet them in I , and K , and the line K, I , will terminate in F , the vanishing point of its original.

The reflection of G , is found on the same principles. In order to find its seat, draw from its lower angle a line parallel to D, S , and a ray from 11 , the angle of the wharf, to S , cutting that parallel in 8 ; drop a perpendicular from 8 , and cut it in 9 , by another ray from the surface of the water, under 11 ; drop a perpendicular from the lower angle of G , and draw $9, 10$, parallel also to S, D , cutting that perpendicular in 10 , which will be the surface of the water; measure therefore from the top of G , to 10 , and repeat that to 12 , which will be the reflexion sought.

Here is introduced a row of trees, to shew in what manner they are to be reflected, and how many of them would be seen. Continue the ray, or line, on which they stand, forwards to the margin, or edge, of the wharf; from thence take the distance to the surface of the water, and repeat it downwards by a perpendicular; and, from the lower extremity of that perpendicular, draw a line to S , and then to that line drop a perpendicular from the first tree; and from this last point of interfection, measure the tree downwards, and mark the top, and stem, of that inverted tree; thence draw lines to S , which lines will receive perpendiculars from each tree above, whose interfections will give the places of the reflected trees, respectively.

And it appears that no more than parts of the three forwardest trees will be visible, in the water, by reflection.

Here, and every where, such objects, and such assemblage of objects, only are represented, as seem best calculated to exhibit examples for the instruction intended, and not any regular figures, or agreeable pictures.

Fig. 74. No. 1. The reflection, or image, of the figure A, supposed to stand before a looking-glass, is found on the same principles as reflections in the water, with this difference, in the process, that the feet on the reflecting plane, and the image beyond, or within it, are both *perspectively* found in this and every vertical situation, except when the object, and its reflected image, are in a line parallel to the picture; whereas in the horizontal, (*i. e.*) in water, they are only, and always found geometrically; therefore, having found the distance from A, the foot of the figure, to *a*, the plane of the looking-glass, on the visual ray A, S, repeat the same distance, on the same ray, onwards, that is, within the glass, to *a*, which will determine the foot of the image; there raise a perpendicular, and draw another ray from the head of the figure to S, cutting that perpendicular, which intersection determines the height of the image; and in like manner any points of the original figure may be found, by drawing rays to S, from such points through corresponding perpendiculars.

And in the same manner is found the image of the figure B, in the glass, before it; but this figure is again reflected in the glass, behind it (which is over the chimney,) by geometrical measures, taking first the distance to the plane of the glass from B, to *b*, and again the same distance to *b*, within the glass; which is an operation so fully explained in the preceding figures (reflected in water) as to need nothing more here: it will be observed, that, in this latter case, the image is always equal to its original, whatever be the distance; whereas, when perspective measures are necessary, the images become less, in proportion to their distance.

As these representations are made purely for instruction, it was necessary to place the figures where the images could be reflected without grouping, or giving them any relation to each other; and for the same reason here are two of the glasses inclining forwards, in order to

Fig. 71. N^o. 5.

Fig. 71. N^o. 4.

Fig. 71. N^o. 3.

Fig. 72. N^o. 1.

Fig. 72. N^o. 2.

Fig. 73.

shew the manner of finding reflections, in such situation; they both incline in an angle, of 18 degrees, with the side of the room; as that opposite to the figure F, whose image is found by the same general law, but the particular circumstances require explanation; and first the vanishing line of the plane of the glass runs through E, below, which is the vanishing point of the sides of it, and the bottom touches the wainscot in the points *c*, and *d*. Wherefore, having drawn E, *c*, and E, *d*, and dropped a perpendicular from *c*, or *d*, to the floor, as here from *c*, to 5, draw S, 5, cutting E, *c*, in 6, through which a parallel to S, D, (as 6, *f*;) will be the bottom of the glass on the floor (supposed beyond the wainscot). Now drawing F, S, cutting 6, *f*, in *f*; and drawing E, *f*, this line will give the indefinite seat of the axis of the figure on the glass, and G, being the vanishing point of perpendiculars to the plane of the glass, draw F, G, cutting E, *f*, in *g*, which is the seat of the foot of the figure; wherefore double, or repeat F, *g*, within the glass perspectively (as has been frequently taught) to *b*, which will be the foot of the image, or reflection in the glass, and also drawing from the head of the figure to G, cutting E, *f*, *g*, in 7, that will be the seat of the head; this distance from the head to 7, being repeated perspectively, finds the head of the image, which is now easily completed, as the others.

The axis of the image might be found, by continuing the axis of the original figure, perpendicularly from F, upwards, till it meets the axis of the seat E, *f*, *g*, 7, in H, and drawing H, I, which will be the axis of the image; for this point I, is the vanishing point of the image, found, by making E, D, I, an angle of 18 degrees.

If the reader finds any difficulty to conceive this operation, or the reason of it, he is referred to the scheme below,

Fig. 74. No. 2. which is a geometrical representation of it, with the same characters. F, *o*, H, is the axis of the original figure; *f*, *g*, 7, H, the section of the glass with the same inclination as in the picture; *g*, 7, is therefore the seat on the glass, and *b*, *o*, the image, which last meets F, *o*, in H, as above. F, *f*, in the geometrical scheme, is the floor; *f*, *b*, the same reflected (the angle of reflection being equal to that of incidence);

cidence); and hence appears the reason of drawing D, I, to find the vanishing point of the image, for this line represents H, *b*, in the geometrical, as D, L, perpendicular to D, I, represents *f*, *b*, in the geometrical; H, *b*, *f*, being also a right angle, and therefore L, is the vanishing point of all the radials in the reflected floor. It may be worth while to examine the correspondence of these lines in the geometrical scheme, and the perspective. The floor reflected in the glass, is represented at 11, 10, above, which are the images of 11, and 10, below, on the first line of the floor, found by drawing lines from the originals to G, (the vanishing point of perpendiculars to the glass,) and cutting them by other lines from the intersection of the glass with the floor; as from P, to L, the vanishing point of the radials on the reflected floor, and (therefore) of perpendiculars to the image. Since therefore the reflected image of 11, must be in each of these lines, it must be in their common intersection. Here are three sets, or pairs of lines, perpendicular to each other; the first pair are D, S, the common distance, and geometrical perpendiculars to it, for the representation of the room, &c. the second pair D, E, and D, G, for the representation of the glass, and the seats of objects on it; and the third pair D, I, and D, L, for the representation of the image, or reflection, of the man, and of the floor, at right angles to the man.

The image of the object K, in the glass M, is found by lines drawn from each point, geometrically perpendicular to the plane of the looking-glass, (which is inclining in the same angle from the wall, as the last, viz. 18 degrees); these points, on the surface of the glass, are seats of the originals, from each of which, an equal distance is taken within, or beyond the surface, which last set of points being joined by right lines, become the image sought. The several seats on this glass are found, by drawing lines, from each original point on the floor, parallel to the horizontal line, cutting the section of the glass on the floor, and thence drawing a parallel to the side of the glass, and drawing a perpendicular to that parallel from the original point. And for any original point above the floor, find its seat first on the floor, and proceed as if that was the point, and then draw a perpendicular from the real
original

original point above, to the parallel on the glass, as before directed.
Or as at

Fig. 74. No. 3. First suppose the glass to be close to the wall, (*i. e.*) to coincide with the line *f, P*, and consequently perpendicular to the floor, both before and behind.

Then (as the glass inclines forwards) the floor, behind, rises in proportion, (*i. e.*) to the pricked line *f, O*, (18 degrees); yet still 90 degrees will be left, between that line, and the back of the glass, from which there must now be taken 18 more by the line *f, g*, to reduce the angle, behind, to 72, equal to that before, which has lost 18, by its inclination forwards.

And this is the reason of the two angles of 18, behind the glass, between *f, N*, and *f, g*.

Draw *A, B*, and its parallels, (from the intersections of *b, A*, and its parallels) all parallel to *f, g*.

Transfer the several divisions of the line *e, f*, on *f, g*, and from these last, draw to *S*, crossing all the parallels of *A, B*, which finishes the reflection of the floor, in the glass.

Every particular has been so repeatedly explained, in relation to the former objects, that nothing need be here added. If any possible difficulty arise, a careful inspection will remove it.—The reader must observe, that though the glass receives but part of the image, yet the whole is described by pricked lines, that the process may be entirely comprehended.

The several numerical figures of the image correspond with those of the originals, respectively.

N. B. 1, 3,—2, 4, at the bottom, and top of the image, No. 1. run to the same vanishing point *S*, as 1, 3, and 2, 4, &c. of the original, with which they correspond; and 1, 2,—3, 4, &c. are, also, parallel to each other, as in the original, being parallel to the picture.

The floor is chequered on purpose, to give occasion for shewing its image, or reflection in the two inclined glasses; and in that marked, *M*, there is also the image of so much of the window nearest to it,

as could be seen, by reflection, in it; as also in the opposite glass over the chimney is the reflection of part of the nearest perpendicular glass, and of the window, and, if the chimney glass had been wider, the very image of B, in the glass before it, would have been again reflected in that of the chimney, where the pricked touches are made, that being the place in which the distance from the image, to the side of the room, is doubled, supposing that side continued on, as far (backwards) as the image is cast.

Though very few designers will, perhaps, take the pains to project, by rule, every reflected object; and though it seldom happens that very intricate dispositions of such objects occur, yet it may not be useless to add two or three cases, in which the principles herein explained, and the methods founded on them, will appear peculiarly advantageous: those who are curious in speculation, and those who desire to be correct in the execution, will be gratified; and all will be better able to judge of what they see, as well as the practitioners will be better able to perform, (even though it be by guess) after knowing, and considering the rules, than without such knowledge, and consideration.

Fig. 75. No. 1. P, Q, R, T, is supposed to be a looking-glass standing, perpendicularly, on the horizontal plane; A, B, E, F, an object to be reflected, which is designedly made plain, and simple, to avoid confusion of lines; draw A, a,—E, e,—B, b, and F, f, all parallel to the horizon, (which lines will be perpendicular to the plane of the glass,) and in these lines will be found both the seat of the object, on the glass, and also its reflection, in it. m , S, is the vanishing line of the glass, and m , C, of the object to be reflected; but as C, (the vanishing point of A, B, and E, F,) is above the horizon, continue m , C, till it cuts the horizontal line in r , and draw E, r , cutting P, Q, S, in n , which will be the point where the two planes, of the glass and object, meet on the ground; and as their vanishing lines meet, above, in m ,—draw m , n , which will be their common intersection, and of which, m , is the vanishing point.

Draw C, L, perpendicular to m , S, the vanishing line of the glass, cutting it in K, then K, will be the vanishing point of the seats of
A, B,

18

D

L

Fig. 74. N° 2.

Fig. 74. N° 3.

Fig. 74. N° 2.

A, B, and E, F, on the plane of the glafs; for C, is their original vanishing point, and K, is perpendicular to it, on the vanishing line of the glafs; and m, n , being the interfection of thefe two planes, and A, B, C, cutting that interfection in o , draw K, o , cutting A, a , in 1, and B, b , in 2, then 1, 2, K, will be the feat of A, B, C; and as E, F, C, alfo cuts the fame line m, n , in V, draw K, V, cutting E, e , in 3, and F, f , in 4; then 3, 4, K, will be the feat of E, F, C, and drawing 1, 3, and 2, 4, the whole feat is completed; and doubling the four parallels A, 1, to a ; B, 2, to b ; E, 3, to e ; and F, 4, to f ; the image is completed, by joining a, b, e, f .

Or, fince the image or reflection is juft as far behind the feat, as the original is before it, in C, K, L, make K, L, equal to C, K, and then L, will be the vanishing point of the image; wherefore draw L, o , cutting A, a , in a , and B, b , in b , and draw alfo L, V, cutting E, e , in e , and F, f , in f , and joining a, e , and b, f , the image is completed; and by this method it may be found, even without the trouble of firft finding the feat.

Or, inftead of drawing four parallels, two will fuffice, A, a , and B, b ; and having drawn L, o , cutting thofe two parallels in b , and a , and continued the fides of the original A, E, and B, F, till they cut the line m, n , in p , and q , draw q, a , and p, b , cutting L, V, in e , and f , this will complete the image alfo, without finding the feat.

Fig. 75. No. 2. Proceed as was fhewn at large in the former figure, which is the univerfal method recommended. The fame letters, and numerical figures, are ufed in this, as in that, to fhew the correpondence. The only difference is, that, as this glafs does not ftand perpendicularly on the horizontal plane, fo the parallels A, a ,—B, b , &c. are not parallel to the horizon, but are *here*, as they muft be, *always*, perpendicular to the reflecting plane.

Fig. 75. No. 3. In this fcheme is the fame general method ufed, as in the two preceding; however, that nothing may be left unexplained, it is to be obferved, that the glafs here is oblique, not (as the laft) on the horizontal plane, but above it, whofe vanishing line is m, K, r , and the vanishing point of the fides R, T, and P, Q, being K, the lines

Q

per-

perpendicular to this plane, are drawn perspectivevly (and not geometrically, as in the two former); that is, the vanishing point *W*, of lines perpendicular to it, is found, by the rules heretofore taught, and *A, W,—B, W,—E, W,* and *F, W,* drawn, representing perpendiculars, and consequently *K, L,* is made perspectivevly (not geometrically) equal to *K, S*: after which the image of the object is found by means of *L*, the vanishing point of its sides; *m, L*, being its vanishing line; and the feat (though not necessary) is found (as before) to shew the conformity of the lines, and of the process, with the preceding schemes.

N. B. As the same letters stand for the same points, it is needless to enter into the explanation over again, except that here, it became necessary to vary two or three; as *K*, for instance, at the same time that it is the vanishing point of the sides of the glass, is also the vanishing point of the seats of *A, B,* and *E, F,* and that the vanishing point of the same original lines *A, B,* and *E, F,* which was marked *C*, in the former schemes, is here marked *S*, because it coincides with the center of the picture, which is always distinguished by the same letter, &c. *n,* and *V,* also coincide in this scheme; *S, D,* is the distance of the picture; and the point *L*, is found by drawing *S, 5, 6,* parallel to *W, D,* drawing *D, K,* cutting it in *5,* making *5, 6,* equal to *S, 5,* and then drawing *D, 6,* cutting *S, K, L,* in *L.*

Fig. 75. No. 4. This last scheme is still by the same method; but that no difficulty might be avoided, the center of the picture is not the vanishing point of either the object, or glass, both which are placed obliquely, the one above, the other below the horizontal line; and as *E,* is the only point of the object that touches the ground (*E, C,* and consequently *F,* being under it) *E, r,* is drawn to the intersection of its vanishing line with the horizontal line, and also *P,* being the only point of the glass that touches the ground, *P, r²,* is drawn to the intersection of its vanishing line with the horizontal line, and *E, r,* cutting *P, r²,* finds *n,* through which, from *m,* (the intersection of two vanishing lines) viz. of the glass, and object, is drawn *m, n,* the inter-

interfection of their two planes. The rest is all as the former, only one letter (viz. Y,) is added here; for S, served in all the former cases as the vanishing point, either of the glass, or of the object, one of which coincided with the center of the picture, but Y, is (in this scheme) the vanishing point of R, T, and P, Q, and Y, S, W, is the vanishing line of a plane perpendicular to Y, *m*, (the vanishing line of the glass) on which Y, D, W, is made a right angle to find W, the vanishing point of perpendiculars.

The four last schemes, Fig. 75. No. 1, 2, 3, and 4, are designed to explain, on the principles of *Brook Taylor*, the method of finding reflected objects in mirrors, and have a more particular reference to the last scheme in his book, where he represents the image of a picture as reflected in a glass standing obliquely on a table. They are exhibited with all possible simplicity, and without any ornament, that so no lines may enter into the diagrams, but such as are absolutely necessary to the projection of the image proposed.

This is one of the parts of that work, which is mentioned (in the Preface of this Treatise) as attended with difficulty. No. 3, is nearly *Brook Taylor's* own example, but with all the necessary lines; No. 1, and 2, are preparatory, and explanatory of the principles; and No. 4, a case still more difficult, but all on the same principles.

C O N C L U S I O N.

THE author has, in this work, endeavoured to express himself with all the perspicuity that the nature of the subject will admit, and has been less solicitous to avoid repetition, than to avoid obscurity. That over scrupulous exactness, which permits not to repeat an instruction (once delivered) though at the distance of many pages, makes references backwards continually necessary, and not only perplexes and wearies the reader, but disgusts him more than, now and then, a seasonable repetition; and the getting by heart a great number of definitions, before their use can be known, especially when most of them will afterwards appear to be unnecessary, is burthen-

some to the memory, and tedious even to patience itself; yet every one of these must be distinctly remembered, or the reader must be continually turning back to analyze them, which interrupts him beyond measure. If, on the contrary, it were thought sufficient to call a shadow, a shadow, to call the ground, the ground, and to give the common names to common things, and to treat this subject in a more familiar way, it might, undoubtedly, be thereby more accommodated to the apprehensions of the generality of those, whose professions require a knowledge of perspective. And this is what the author has endeavoured to execute.

He is far from saying, or thinking (as the Jesuit in his Preface) "That perspective is the very soul of painting, and which, alone, can make the painter a master;" or as some others, who may have set it too high among the requisites, in forming a painter; since many very great masters have been deficient in it, some egregiously, who have, notwithstanding, possessed the other, and more excellent parts in a high degree; as invention, composition, expression, correctness of design, and colouring; which will produce fine pictures, though the perspective be, in some respects, faulty, and much finer, than any, in which the perspective may be absolutely true, and these other parts but in a low degree.

It is certain, however, that perspective is an essential, and that whatever is erroneous in this respect, does not truly represent the thing intended; that it is absolutely necessary to the perfection of painting; and that some subjects, particularly architecture, cannot be represented without it. It is also certain that a man will invent, and compose with more facility, and precision, who understands it well, than he who understands it but imperfectly, supposing other qualifications equal; that great errors in it are monstrous, and shocking, and that a total ignorance of it is unpardonable in a painter, or designer.

The E N D.

THE

S U P P L E M E N T .

T H E

S U P P L E M E N T :

Added to illustrate and explain some of the more difficult parts of the foregoing Treatise, which, in their several places, were necessarily complicated; but are here separated, in order to their being singly, and distinctly considered. For this purpose it has been thought most convenient to repeat the same figures and numbers as in the body of the work, where the same subjects are treated (with the addition, only, of capital letters) that reference may easily be had to such places.

A N D F I R S T,

TH E reader is referred back, from this place, to Fig. 71. No. 1. where he will find, that the vanishing point O, of the post 11, 12, is at a considerable distance below, among other objects, and (on that account) not so readily distinguished; and, also, that the vanishing point of its shadow is beyond the limits of the plate. For these reasons it has been thought proper to repeat this diagram by itself, and in a narrower compass, that all the points may be seen at once, and so their relation more distinctly appear, especially as this is a matter of some difficulty, and of great use.

Fig. 71. No. 1. A.—11, 12, is a line standing obliquely on the horizontal plane, whose seat is 13, 12, and the vanishing point of that seat is S.—U, is the given vanishing point of the sun's rays. First find the vanishing point of 11, 12, by dropping a perpendicular from S, and continuing 11, 12, till it cuts that perpendicular in O, which will be its vanishing point; then draw from O, through U, to the horizontal line, cutting it in X, which will be the vanishing point of the shadow; then draw 11, U, and 12, X, cutting it in 14; then 12, 14, is the shadow sought. For U, V, cutting the horizontal line (perpendicularly over U,) in V, this will be the vanishing point of the shadow
of

of any line standing perpendicularly on the ground. Now if such a perpendicular line 11, 13, be drawn, cutting the feat in 13, the shadow of that perpendicular will be 13, 14, and 14, will be (in that case, also,) the shadow of the point 11; therefore 12, 14, must be the shadow of the whole line 11, 12, which is a proof, that the first operation was true.

All the references are the same as in the large scheme, and there is no difference in any circumstance, except that this post leans forwards in an angle of 58, and the former in 65; which change was made, only to avoid the too great distance of the vanishing points O, and X.

So that if the text, relating to the former, be read with this scheme, it will answer throughout.

And this will be general, for any line, viz. to draw from its vanishing point, through the vanishing point of the ray of light, to the vanishing line of the plane on which the shadow is to be projected, whether it be the horizontal plane, or any other; and this intersection, with the vanishing line of the plane on which the shadow is cast, will be the vanishing point of the shadow. For, (in this scheme,) imagine the plane D, S, O, raised on S, O, till D, S, be perpendicular to the picture; then a line from D, to U, determines the vanishing point of the rays; and, consequently, a line through O, and U, to the vanishing line of the horizon, will give the vanishing line of the plane of rays passing over the whole line O, 12, 11, and therefore, also, the vanishing point of the shadow 12, 14.

Fig. 71. No. 1. E. Is an example of the same kind on an oblique plane. Here C, *q*, is the vanishing line of such plane; Q, P, a vanishing line of planes perpendicular to it; *a*, B, a line standing perpendicularly on the plane C, *q*;—B, its feat, on that plane, and P, its vanishing point; U, the given vanishing point of the rays of the sun, and V, the vanishing point of the shadow, found as X, in the last; that is, by drawing from P, the vanishing point of the line *a*, B, through U, the vanishing point of the rays, to the vanishing line of the plane on which the shadow is cast; draw *a*, U, and B, V, cutting it in *e*, then *e*, is the shadow of *a*, and B, *e*, of B, *a*, on the plane C, *q*.

And if any other line, as a, b , be given, on the same plane C, q , standing obliquely on it (yet being parallel to the plane Q, P ,) continue that line a, b , to its vanishing point Q , and draw Q, U , cutting C, q , in q , then q , will be the vanishing point of its shadow on the plane C, q . Wherefore,

Draw b, q , cutting the ray a, U , in e , and b, e , will be its shadow.

If a, B , were continued to g , then g, b , would be the shadow of a, g .

And if a, b , were continued to f , (or any length) the same operation finds the shadow; thus f, b , is the shadow of a, f , &c.

Fig. 71. No. 1. F. Here is one more example for the shadows of oblique lines. These incline inwards, and therefore have their vanishing points above the horizontal line.

O, H , the horizontal line; Y , the vanishing point of the four lines A, B ;— U , the vanishing point of the rays of light, and consequently U, Y , is the vanishing line of the rays which pass over these four lines; and W , (being the point, in that vanishing line, which cuts the horizontal line) is the vanishing point of their shadows on the horizontal plane, (*i. e.*) on the ground. The line A, L , being in a different direction, has another vanishing point, viz. y , and therefore the rays passing over it will produce another vanishing line, as U, y , which cutting the horizontal line in w , that becomes the vanishing point of the shadow on the ground of this line A, L .

The rest needs no explanation, only as H , is the perpendicular seat of Y , on the horizontal line, and b , of y ; if the perpendicular seats of A , are found, then, by means of these seats, the same shadows might be determined, as in the case of perpendicular lines; for the shadows of the point A , would exactly coincide with these, here, found, and then the point o , perpendicular to U , must be used as the vanishing point of these shadows on the ground.

The seat of any of the points A , is found by drawing a line from B , to H , then dropping a perpendicular from A , to the line B, H , which line is the seat of the line A, B , on the ground, as at $A, 1$, and at $A, 2$, the seat is a ; and then drawing a, o ; and A, U , inter-

fecting it in a , this point is the shadow of A , which coincides with that already found, and is a proof, that the method, proposed, is universally true.

N. B. The center and distance are not given, being no way concerned in this diagram, for wherever the center is placed, in the horizontal line, or whatever be the distance, all the several relations of these lines remain the same.

It is also evident, that two lines, only, are necessary to the determining any shadow, as appears at $A, B, 4$, viz. one from the top A , to the vanishing point of the rays U , and another from the bottom B , to the vanishing point of the shadow W ; the additional lines at 1 , and 2 , are merely for illustration, or proof; and at 3 , there is another line A, L , whose vanishing point is y , and the vanishing point of its shadow w .

The foregoing schemes have been introduced, and explained, in order to facilitate the practice, in the perspective of shadows, and principally with respect to the members of architecture; for though, hitherto, in simple lines, only, (that they may be more easily comprehended,) yet their application, and utility will appear by those which follow.

Fig. 69. No. 1. (in the foregoing treatise) is the representation of a Doric cornice; now to find the shadows of the projecting members, draw from S , (the center of the picture) a line to the extremity of any member, (*e. g.*) to f , the extreme angle of the modillion; which line will be (perspectively) perpendicular to the plane of the picture, and find the point g , in which such member touches the naked, or solid, of the building, (*i. e.*) the plane on which the shadow is to be cast; and from that point g , draw a line g, b , parallel to S, R , (R , being the given vanishing point of the rays of light); then draw f, R , cutting g, b , in b , which will be the shadow of f ; and so of the rest.

Fig. 69. No. 1. A. But to explain this operation, unembarrassed with other lines, is the following scheme. Here S , is the center of the picture; S, D , the distance; R , the vanishing point of the rays of the sun; f, g , a line perpendicular to the picture, and also to the plane

on which the shadow is to be cast, which plane is parallel to the picture. Now, g , being the seat of f , g , on the parallel plane, or the point in which it touches that plane, draw g, b , parallel to S, R , and draw f, R , cutting it in b ; then g, b , will be the shadow of g, f .

For as all lines tending to S , represent lines parallel to D, S , when raised up on S , (*i. e.*) perpendicular to the picture; so all lines tending to R , represent lines parallel to D, R ; therefore S , is the vanishing point of all the lines f, g , and R , of all the rays passing over them, which rays (though parallel among themselves) being oblique to the picture, must have a common vanishing point. And as the plane, on which these shadows are cast, is parallel to the picture; and the objects, whose shadows are sought, all perpendicular to that plane; the shadows must necessarily be all parallel to each other, and to the seat of the rays on that plane, which is S, R , and therefore can have no vanishing point; and for the same reasons, all perpendicular objects, that are of equal length, will project shadows, on this parallel plane, of equal length also.

Fig. 69. No. 1. E. As for the side plane of the same object, which plane is perpendicular to the picture, the shadows will have a vanishing point, as Z , perpendicularly under S , for S, Z , is the vanishing line of that plane, and R, Z , drawn from R , perpendicular to S, Z , will be parallel to the lines, whose shadows are sought, on this plane, which lines are all parallel to the picture. Thus, draw a line from i , (the point where l, i , touches the side or profile of the building) to Z , and then draw another line, l, R , cutting it, in m , which will be the point sought, that is, the shadow of l , on the solid of the building, exactly as on the horizontal plane in finding the shadow of a line standing perpendicularly on it; for (turning the picture) the whole corresponds to that; and having found m , the shadow of any such point l , draw S, m , which will determine the whole shadow of such projecting member; for S, m , represents a line parallel to i, i , and l, l .

To find the shadows on a plane oblique to the picture, such as at Fig. 69. No. 4. (in the foregoing treatise) a line must be drawn (perspectively) perpendicular to that plane, (*i. e.* as the modillions are, on this face of the building,) and then the operation will be like the last; but as there, space is wanting to introduce the vanishing points of the rays, and of the shadow, see

Fig. 69. No. 4. G.—Draw b, A , to its vanishing point g , and from g , draw through R , the given vanishing point of the rays, to S, e , (the vanishing line of this face of the building,) cutting it in e , which will be the vanishing point of the shadow. Now draw b, R , and A, e , cutting it in f , then A, f , is the shadow of A, b , on this plane. These are all the lines that are necessary for the purpose; and this is the shortest method.

But the shadow f , of the point, b , might be found by other lines, which are here added merely for illustration, and to shew a kind of correspondence.

For, in every method, the truth of the operation depends upon the similarity of triangles, either geometrically, or perspectively, and in this already explained, the triangles b, A, f , and R, e, f , are perspectively similar, that is, represent similar triangles; for g, b , and g, e , represent parallel lines, as having the same common vanishing point g .

And if R, L , be drawn parallel to S, g , (the horizontal line) cutting the same vanishing line S, e , in L , and b, a , be drawn parallel to it, then draw a, L , which cutting b, R , finds the same point f , for the shadow of b , and here the triangles b, a, f , and R, L, f , are, geometrically, similar.

Again, if a perpendicular from R , be drawn cutting S, g , in r , draw r, b , cutting S, A , in a , and draw a, f , parallel to r, R , this also will cut the ray b, R , in the same point f , and here the triangles b, a, f , and b, r, R , are similar.

And having found f , the shadow of b , draw S, f , which will determine the whole shadow of the projecting member; *as in the last example.* For S, f , represents a line parallel to S, A , and S, b .

Fig. 72. No. 1. A. This scheme is introduced to explain some particulars relating to the shadow of the ladder at Fig. 72. No. 1. and therefore

Fig. 69. N^o. 1. A.

Fig. 71. N^o. 1. F.

Fig. 69. N^o. 1. E.

Fig. 69. N^o. 1. G.

fore has the same letters, and numerical figures of reference; only instead of that object, here is a plank, in order to shew the operation and effect more distinctly.

G, Θ , 4, is a ray parallel to the plank, and the triangle G, 4, S, is a plane of rays continued to the horizon.—A, 7, is the intersection of that plane, by the plane of the wall against which the plank leans: therefore from the point A, (the top of that intersection) drawing A, 5, and A, 6, through the top of the plank, these lines will give the shadow of it on the wall, but being interrupted by the door, at 13, 14, the shadow will thence take another direction. Now since the plane of the door (whose vanishing point is *a*,) cuts the triangular plane of rays in B, 8, (*as the plane of the wall does in A, 7,*) therefore from the point B, draw through 13, 14, which will give the direction of the shadow on the door, which shadow will meet that on the ground (from the bottom of the plank) in 11, 12. The triangle B, 11, 12, corresponding to the plane of the door, exactly as the triangle A, 5, 6, does to the plane of the wall, and as the triangle 4, F, G, does to that of the utmost distance, which, being parallel to the picture, and to the wall, the line 4, G, is parallel to A, 6, and 4, F, to A, 5, which shews the correspondence of the operation, and proves the truth of it.

And as *a*, is the vanishing point of the top, and bottom of the door, so *a, g, f*, will be the vanishing line of its plane; wherefore, continuing 11, B, to *g*, and 12, B, to *f*, these will be the vanishing points of those lines;—and as *a, g, f*, is at the utmost extent, or on the horizontal line, as well as F, 4, and G, 4, so, by continuing F, 4, to *f*, and G, 4, to *g*, these same points *f*, and *g*, will also be the intersections of the vanishing lines F, 4, and G, 4, with the vanishing line *a, g, f*, which is a farther illustration of the whole.

N. B. It seems hardly necessary to add, that G, (being the point in which the same ray 4, Θ , G, touches the ground) answers the same purpose for the plane of the ground, as A; and B, for the planes of the wall, and the door, and that the triangle G, 11, 12, on the ground (therefore) corresponds to that plane, as A, 13, 14, and B, 11, 12, to their respective planes.

As

As a farther illustration of the two last schemes, and to render this kind of operation (which is of great use) still more clear, here is added a third.

Fig. 72. No. 1. B. Let $L, 4$, be considered as one leg of the ladder, or a pole, continued to its vanishing point 4 ;— L, S , the feat of the pole, on the ground, continued to its vanishing point S ; so that $L, 4, S$, may be considered as a triangular plane, whose vanishing line is $S, 4$. Draw from 4 , through Θ , the light, and from S , through F , the foot of that light, meeting in G , which will be the foot of the light, for the pole, because $4, G$, represents a parallel to $4, L$.

Draw G, L , cutting $a, 11$, (which is the intersection of the plane of the door with the ground) in b , and from 8 , (the intersection of L, S , with $a, 11$.) raise a perpendicular, cutting $L, 4$, in d ; draw b, d , which will be the shadow of L, d , on the plane of the door; continue b, d , till it meets a, f , (the vanishing line of the plane of the door) in f , which will be the vanishing point of b, d .

Or that vanishing point may be found, by continuing G, L, b , to F , in the horizontal line, and drawing $F, 4$, which will find the same point f , and then drawing b, f , which will cut $L, 4$, in d .

And this last method will be true for any plane, whose vanishing line is a, f .—For suppose a plane whose intersection with the ground is $a, 7$, and which is cut by L, S , in b ; raise, at b , a perpendicular up to $L, 4$, cutting it in k , and draw $7, k$, which will tend to the same point f ; or draw $7, f$, which will cut $L, 4$, in k , and $7, k$, will be the shadow of L, k , on that plane.

And so universally of any plane, whose vanishing line is a, f , from $a, 11$, to a, F .

Again, suppose a line drawn through L , parallel to the horizontal line a, F , cutting $4, \Theta, G$, in g , and $a, 11$, in 11 , and S, g , cutting Θ, F , in f , then f , will be the foot of the light (removed farther within the plane of the ground); and drawing $4, U$, parallel to $g, L, 11$, cutting the vanishing line a, f , in U , then U , will be the vanishing point of the shadow of $L, 4$, (or of L, d .) on the plane of the door; and drawing $11, U$, cutting $L, 4$, in d ,— $11, d$, will be that shadow;

remem~~r~~

Fig. 72. N.º 1. A

remembering, that in this last case, the foot of the light is supposed to be f , (farther removed within the picture) which occasions the shadow from g , to be so much longer, than that from G , produced by the foot F , which is nearer; and that, in either case, \odot , (the light) is just as far within the picture, or the ground, as its foot, whether it be F , or f .

Fig. 72. No. 3. Here the rays of light, are those of the sun, supposed to be parallel to the picture, and to H, I ; it is required to find the shadow of the square projection a, b, c , of this building on the parts contiguous to it.

First, draw c, q , parallel to K, I , the horizontal line, this gives that part of the shadow which is cast on the ground; at q , raise a perpendicular to r , the edge of the roof; then draw r, n , parallel to K, L , the vanishing line of the plane of the roof, and draw b, n , parallel to H, I , cutting r, n , in n , which is the shadow of b ; so that c, q, r, n , is the whole shadow of the line c, b , and is, evidently, in a plane of rays parallel to the picture, and to H, I .

For c, q , is on the horizontal plane, and parallel to the horizontal line, and q, r , is parallel to c, b , and in the same plane with that, and c, q ; and r, n , (joining q, r ,) is on the roof, and parallel to its vanishing line L, K ; therefore, &c.

Now, in order to find the shadow of b, a , whose vanishing point is I , let it be considered that I, H , is the vanishing line of the plane of rays which pass over b, a , and L, K , is the vanishing line of the roof, and, therefore, that the intersection of these two vanishing lines E , must be the vanishing point of the shadow of b, a , on the roof, *for the shadow itself is the intersection of those two planes*. Therefore draw E, n , which will be the indefinite shadow of b, a , on the roof, and drawing a, o , parallel to H, I , cutting E, n , in o , this would determine o, n , the shadow of a, b , (for o , would be the shadow of a , on the roof) if the roof were continued so high; but as this is interrupted by the perpendicular plane l, o , whose vanishing line is K, H , which intersecting I, H , (the vanishing line of the rays) in H , this intersection will be the vanishing point of the shadow on that plane, *for this shadow is the intersection of the rays with that plane*. There-
fore

fore draw H, *a*, cutting *n*, *o*, in *p*, and then *a*, *p*, is that part of the shadow of *a*, *b*, which falls on the wall, and *p*, *n*, the rest of it, which falls on the roof; so that *a*, *p*, *n*, is the whole shadow of *a*, *b*, produced by rays all parallel to the picture, and to H, I.

And to prove the truth of all this, draw from *c*, the seat of *b*, on the ground, and from *e*, the seat of *a*, two lines, *c*, *g*, and *e*, *f*, parallel to the horizontal line; then draw *b*, *g*, and *a*, *f*, both parallel to H, I, cutting them in *g*, and *f*; then *g*, will be the shadow of *b*, and *f*, the shadow of *a*, on the ground. And, having continued I, *e*, *c*, and L, *b*, till they meet in *i*, draw K, *i*, and I, *f*, *g*, meeting in X; draw X, L; now raise perpendiculars from *g*, and *f*, cutting X, L, in *l*, and *k*; draw *k*, *b*, and *l*, *m*, which will be perpendicularly over *f*, *e*, and *g*, *c*, and parallel to each other, and to the vanishing line L, K, and therefore will be the shadows of *a*, *b*, and *b*, *m*, on the roof; which lines meeting with the rays *b*, *g*, and *a*, *f*, in *n*, and *o*, these rays determine the lengths of the shadows; that is, *n*, is the shadow of *b*, and *o*, would be the shadow of *a*, if the roof reached so high; in which case, *o*, *n*, would be the shadow of *a*, *b*; but as the roof is interrupted by the perpendicular plane above, (which touches the line *b*, *p*, in *p*.) therefore *a*, *p*, will be so much of the shadow of *a*, *b*, as falls on that plane, and the rest of it is *p*, *n*, on the roof.

Fig. 72. No. 4. Is a cylinder, lying on the ground, whose base is parallel to the picture.

S, is the center of the picture; R, the vanishing point of the rays of light, which are supposed to come from the sun; L, the vanishing point of the shadow, found by raising a perpendicular from R, up to the horizontal line; it is required to find the shadow of any point, or points, of the circumference of the base of the cylinder, on the inner surface of it.

The shadow of A, is found on the inner surface, by drawing A, *a*, parallel to S, R, and drawing *a*, S, and, lastly, A, R, cutting *a*, S, in *a*.

For the shadow of A, must be determined by the ray, passing over that point, to the vanishing point R, and it must be in the line *a*, S,

in

Fig. 72. N^o. B.

Fig. 72. N^o. 3.

Fig. 72. N^o. 4.

in which that ray cuts the inner surface, and also it must be in the point (of a, S) in which A, R , cuts that line: therefore it must be the point a .

And so for any other point, or points of the circumference: by which operation a number of points in the inner surface may be found sufficient to trace the shadow of the circumference, within the hollow of the cylinder.

The shadow within the other cylinder is found in the same manner; but that is introduced, principally, to shew the method of finding the shadow cast on the outer surface, by any object, as B , interposed between it, and the light. In order to which; first find the shadow of that object on the ground, then mark any point on the base of the cylinder, as b , and find its seat c , on the ground: draw c, S , cutting the shadow of B ; in d ; at d , raise a perpendicular, and draw b, S , cutting that perpendicular in e , which will be the point of shadow sought. And repeating the same operation for as many points as shall be necessary, the whole shadow of the object B , may be found on the outer surface.

For, b, c, d, e , may be considered as a perpendicular plane touching the cylinder in the line b, e ; and d, e , would be the shadow of B , on such plane; but, as the cylinder is circular, the plane of the shadow touches it only in the point e , which is the reason that other points must be found, by the same method; that is, by marking several points on the base of the cylinder, finding their seats on the ground, then drawing lines from those seats to S , cutting the shadow of B , on the ground, and thence raising perpendiculars; and lastly, drawing lines from the several points (marked on the base) to S , meeting their respective perpendiculars in the points of shadow.

The END *of the* SUPPLEMENT.

DIRECTIONS to the BOOKBINDER.

The two unnumbered Plates to be placed in the Introduction as paged, to wit, x and xii, and those numbered as follow.
